Inference for Zero Inflated Truncated Power Series Family of Distributions

Abstract

Zero-inflated data indicates that the data set contains an excessive number of zeros. The word zero-inflation is used to emphasize that the probability mass at the point zero exceeds than the one allowed under a standard parametric family of discrete distributions. Gupta et al. [1], Murat & Szynal [2], Patil & Shirke [3] have contributed to estimation and testing of the parameters involved in Zero Inflated Power Series Distributions. If the data set under study does not contain observations after some known point in the support, we have to modify Zero Inflated Power Series Distribution (ZIPSD) accordingly in order to get better inferential properties. Zero Inflated Truncated Power Series Distribution (ZITPSD) is one of the better options. In the present work we address problem of estimation for ZITPSD with more emphasis on statistical tests. We provide three asymptotic tests for testing the parameter of ZITPSD, using an unconditional (standard) likelihood approach, a conditional likelihood approach and the sample mean, respectively. The performance of first two tests has been studied for Zero Inflated Truncated Poisson Distribution (ZITPD). Asymptotic Confidence Intervals for the parameter are also provided. The model has been applied to a real life data.

Keywords: Zero Inflation; Zero Inflated Power Series Distribution; Zero Inflated Truncated Power Series Distribution; Zero Inflated Truncated Poisson Distribution

Introduction

In certain applications involving discrete data, we come across data having frequency of an observation ‘zero’ significantly higher than the one predicted by the assumed model. The problem of high proportion of zeros has been an interest in data analysis and modeling. There are many situations in the medical field, engineering applications, manufacturing, economics, public health, road safety epidemiology and in other areas leading to similar situations. In highly automated production process, occurrence of defects is assumed to be Poisson. However, we get no defectives in many samples. This leads to excess number of zeros. Models having more number of zeros significantly are known as zero-inflated models.

In the literature, numbers of researchers have worked on family of zero-inflated power series distributions. Gupta et al. [1] have studied the structural properties and point estimation of parameters of Zero-Inflated Modified Power Series distributions and in particular for zero-inflated Poisson distribution. Murat & Szynal [2] have studied the class of inflated modified power series distributions where inflation occurs at any of the support points. Moments, factorial moments, central moments, the maximum likelihood estimators and variance-covariance matrix of the estimators are obtained. Murat & Szynal [2] extended the results of Gupta et al. [1] to the discrete distributions inflated at any point.
Zero-Inflated Truncated Power Series Distribution (ZITPSD)

Before we define truncated ZIPSD, we first consider the Truncated Power Series Distribution (TPSD) truncated at the support point ‘t’ onwards, where ‘t’ is known. Then the probability mass function of TPSD is given by

\[ P(X = x) = \frac{b_x \theta^x}{f(\theta)(1 - P(X > t))}, \quad \text{for } x=0,1,2,...,t \]

where \( G(\theta) = \sum_{y=0}^{t} b_y \theta^y \) is given by

\[ G(\theta) = \frac{\pi b_x \theta^x}{G(\theta)} \quad \text{for } x=1,2,3,...,t \quad \text{... (2.1)} \]

where \( G(\theta) = \sum_{y=0}^{t} b_y \theta^y \).

It is clear that the truncated distribution is also Power series distribution. Based on the same, we define ZITPSD as follows:

Let the probability mass function of a random variable \( X \) is given by

\[ P(X = x) = \left\{ \begin{array}{ll}
1 - \pi + \pi \frac{b_0}{G(\theta)} & \text{for } x=0 \\
\frac{\pi b_x \theta^x}{G(\theta)} & \text{for } x=1,2,3,...,t 
\end{array} \right. \quad \text{... (2.2)} \]

where \( G(\theta) = \sum_{y=0}^{t} b_y \theta^y \).

**Estimation of \( \pi \) and \( \theta \)**

**Estimation of the parameters using full likelihood function:**

Suppose a random sample \( X_1, X_2, ..., X_n \) of size \( n \) from ZITPSD is available. Then the likelihood function is given by

\[ L(\theta, \pi; X) = \prod_{i=1}^{n} \left( 1 - \pi + \pi \frac{b_0}{G(\theta)} \right) \frac{\pi b_x \theta^x}{G(\theta)} \quad \text{... (2.3)} \]

where \( a_x = 0 \) if \( x = 0 \) and \( a_x = 1 \) if \( x = 1,2,3,...,t \) \( \text{... (2.2)} \)

then,

\[ \log L(\theta, \pi; X) = \sum_{i=1}^{n} \left( 1 - \pi + \pi \frac{b_0}{G(\theta)} \right) a_i \log \pi_x \theta^x + \sum_{i=1}^{n} a_i \log b_x \theta^x - \sum_{i=1}^{n} a_i \log G(\theta) \quad \text{... (2.3)} \]

Maximum likelihood estimators of \( \theta \) and \( \pi \) are obtained by solving the following two equations

\[ \hat{\pi} = \frac{(n - n_0) G(\hat{\theta})}{n G(\theta) - b_0} \quad \text{... (2.4)} \]

\[ \sum_{i=1}^{n} a_i x_i \hat{\theta} = \frac{n_0 \hat{\pi} b_0 G(\hat{\theta})}{G(\theta)^2 \left(1 - \hat{\pi} + \frac{b_0}{G(\theta)}\right)} + \sum_{i=1}^{n} a_i G(\hat{\theta}) \quad \text{... (2.5)} \]

Substituting \( \hat{\pi} = \frac{(n - n_0) G(\hat{\theta})}{n G(\theta) - b_0} \) in eq. (2.5) we get

\[ \hat{\pi} = \frac{G(\hat{\theta})}{G(\theta) - b_0} \quad \text{... (2.6)} \]

which is non-linear equation in \( \theta \). Using Newton-Raphson method first we find \( \hat{\theta} \), substituting this value of \( \hat{\theta} \) in Eq. (2.4) we find \( \hat{\pi} \). The Fisher information matrix of \( G(\hat{\theta}) \) is given by

\[ I(\hat{\theta}) = \begin{pmatrix}
-I_1 & -I_{12} \\
-I_{12} & -I_{22}
\end{pmatrix}
\]

Where

\[ I_{11} = \frac{n G(\theta) - b_0}{\pi G(\theta) - \pi G(\theta) + b_0} \quad \text{... (2.7)} \]

\[ I_{12} = \frac{n b_0 G(\theta)}{G(\theta) - \pi G(\theta) + \pi b_0} \quad \text{... (2.8)} \]

\[ I_{22} = n \pi b_0 \left( G(\theta)^2 G(\theta) - 2 G(\theta) G(\theta) \right) \left( G(\theta)^2 - G(\theta) \right) \quad \text{... (2.9)} \]

Assuming that conditions required for asymptotic normality for maximum likelihood estimators are satisfied, we have following theorem:

**Theorem 2.1:** Let \( X_1, X_2, ..., X_n \) be a random sample from ZITPSD with parameters \( \pi \) and \( \theta \). Then the maximum likelihood estimator obtained by solving eq. (2.4) and eq. (2.6), have asymptotic bivariate normal distribution with mean vector \( (\pi, \theta)' \) and dispersion matrix \( I^{-1}(\hat{\theta}) \) for \( n \) sufficiently large.

That is as \( n \to \infty \), \( \left( \sqrt{n} (\hat{\pi} - \pi), \sqrt{n} (\hat{\theta} - \theta) \right) \to N_2(0, I^{-1}(\hat{\theta})) \).

In the following we present conditional likelihood approach and obtain MLEs for \( \theta \).

**Conditional likelihood function approach:** We observe that the conditional density of \( X_i \) given \( A = a_i \) is independent of inflation parameter \( \pi \), since

\[ P(X_i = x_i | A = a_i) = \frac{b_i (\theta^x / G(\theta) - b_0)^{a_i}}{G(\theta) - b_0} \quad \text{... (2.10)} \]
Now the conditional log likelihood function is given by
\[
\log L'(θ; X) = \sum_{i=1}^{n-n_0} \log b_i + \sum_{i=1}^{n_0} x_i \log(θ) - \sum_{i=1}^{n-n_0} \log(G(θ) - b_i) \quad (2.11)
\]

The mle \( \hat{θ} \) of \( θ \) is the solution to an equation
\[
π_\theta = \frac{\hat{G}'(θ)}{(G(θ) - b_i)} \quad (2.12)
\]

where \( \pi_\theta = \frac{\sum_{i=1}^{n-n_0} x_i}{n-n_0} \) is the mean of the positive observations only. We note that mle of \( θ \) based on full likelihood (eq. 2.6) and based on conditional likelihood (Eq. 2.12) are the same and
\[
AV_\theta(θ) = \left( \frac{G'(θ)}{G(θ) - b_i} + \frac{G'(θ)(G(θ) - b_i) - G'(θ)^2}{(G(θ) - b_i)^2} \right)^{-1} \quad (2.13)
\]

Assuming that Cramer-Huzurbazar conditions required for asymptotic normality for MLEs are satisfied, we have the following theorem:

**Theorem 2.2:** Let \( X_1, X_2, ..., X_n \) be a random sample from ZITPSD with parameters \( π \) and \( θ \). Then the mle of \( θ \) is solution to the eq. (2.12) and has asymptotic normal distribution with mean \( π \mu(θ) \) and variance \( \frac{π}{n}, π(θ) \), for \( n \) sufficiently large. The moment estimator of \( θ \) has asymptotic normal distribution with mean \( π \mu(θ) \) and variance \( \frac{π^2(θ)}{n} \), for \( n \) sufficiently large.

That is as \( n \to ∞ \), \( \frac{1}{n} \left( \pi_\theta - π_θ \right) \to N(0, \frac{π^2(θ)}{n}) \).

**Tests for the parameter \( θ \) of ZITPS distribution**

**Test based on \( \hat{θ} \):** Suppose we wish to test \( H_0: θ = θ_0 \) vs \( H_1: θ ≠ θ_0 \). Let us assume that \( π \) is known. Therefore, under \( H_0 \), from Theorem (2.1) we have
\[
\left( \hat{θ} - θ_0 \right) \sim AN\left(0, AV_θ(θ_0)\right) \quad (2.16)
\]

Define a test statistic to be \( Z_i = \frac{\hat{θ} - θ_0}{\sqrt{AV_θ(θ_0)}} \). Based on \( Z_i \) we define the test \( ψ_i \), which rejects \( H_0 \) at \( α \) level of significance, if \( \left| Z_i \right| ≥ z_{α/2} \), where \( Z_{1-α/2} \) is the upper 100(\( α/2 \))\( n \) percentile of SNV.

Let \( ϕ(\cdot) \) be the cumulative distribution function of SNV. Then the power of the test \( ψ_i \) is given by
\[
β_{ψ_i}(π, θ) = 1 - ϕ\left(\frac{\sqrt{AV_θ(θ_0)}}{\sqrt{AV_θ(π, θ)}} \cdot \frac{\hat{θ} - θ_0}{\sqrt{AV_θ(θ_0)}}\right) \quad (2.17)
\]

where \( \hat{θ} = (n-n_0)/(f(\hat{θ}) - b_i) \).

Based on \( Z_i \), we propose a test \( ψ_i \) accepts \( H_0 \) at \( α \) level of significance, if \( \left| Z_i \right| < z_{α/2} \).

Below we develop tests based on \( \hat{θ} \), estimator based on conditional likelihood approach.

Test based on \( \hat{θ} \): Theorem (2.5) gives
\[
\left( \hat{θ} - θ_0 \right) \sim AN\left(0, A\theta(θ_0)\right) \quad (2.19)
\]
Hence, we define test statistic \( Z^2 = \frac{\hat{\theta} - \theta_0}{\sqrt{AV_\theta(\theta_0)}} \). A test based on \( Z^2 \) which rejects \( H_0 \) at \( \alpha \) level of significance, if \( |Z^2| > z_{1-\alpha/2} \).

The power of the test \( \psi \) is given by
\[
\beta_{\psi}(\pi, \theta) = 1 - \Phi(B) + \Phi(A), \quad ...(2.21)
\]
where, \( A = \frac{\theta_0 - \theta - z_{1-\alpha/2} \sqrt{AV_\theta(\theta_0)}}{\sqrt{AV_\theta(\theta_0)}} \), \( B = \frac{\theta_0 - \theta + z_{1-\alpha/2} \sqrt{AV_\theta(\theta_0)}}{\sqrt{AV_\theta(\theta_0)}} \).

Test based on the moment estimator \( \hat{\theta} \) of \( \theta \): It is clear that the problem of testing \( H_0: \theta = \theta_0 \) vs \( H_1: \theta \neq \theta_0 \) is equivalent to testing \( H_0: \mu(\theta) = \mu(\theta_0) \) vs \( H_1: \mu(\theta) \neq \mu(\theta_0) \), where \( \mu(\theta) = -G(\theta) / G(\theta_0) \).

We have from Theorem (2.3), sample mean is consistent and asymptotically normal for the population mean.

That is \( \bar{X} \sim AN\left( \mu(\theta), \frac{\sigma^2(\pi, \theta)}{n} \right) \).

Therefore, under \( H_0 \), we have
\[
\sqrt{n} \left( \frac{\bar{X}}{\pi} - \mu(\theta_0) \right) \sim AN\left( 0, \frac{\sigma^2(\pi, \theta_0)}{\pi^2} \right).
\]

Define test statistic
\[
Z^2 = \frac{\sqrt{n} \left( \frac{\bar{X}}{\pi} - \mu(\theta_0) \right)}{\sqrt{\sigma^2(\pi, \theta_0)}} \sim N(0,1), \text{ when } \pi \text{ is known.}
\]

The test \( \psi \) rejects \( H_0 \) at \( \alpha \) level of significance if \( |Z^2| > z_{1-\alpha/2} \).

That is, reject \( H_0 \) if
\[
\sqrt{n} \left( \frac{\bar{X}}{\pi} - \mu(\theta_0) \right) \geq z_{1-\alpha/2} \cdot \frac{\sqrt{\sigma^2(\pi, \theta_0)}}{\pi^2}.
\]

The power of the test \( \psi \) is given by
\[
\beta_{\psi}(\pi, \theta) = 1 - \Phi\left( B^\prime \right) + \Phi\left( A^\prime \right), \quad ...(2.21)
\]
where \( A^\prime = \frac{\mu(\theta_0) - z_{1-\alpha/2} \sqrt{\sigma^2(\pi, \theta_0)}}{n \pi^2} \) and
\[
B^\prime = \frac{\mu(\theta_0) + z_{1-\alpha/2} \sqrt{\sigma^2(\pi, \theta_0)}}{n \pi^2}.
\]

If \( \pi \) is unknown, we modify the test statistic by replacing \( \pi \) by its estimate \( \hat{\pi} \) under \( H_0 \). By doing so, we define test statistic
\[
Z^2 = \sqrt{n} \left( \frac{\bar{X}}{\hat{\pi}} - \mu(\theta_0) \right) \sim AN\left( 0, \frac{\hat{\pi}}{\sqrt{\sigma^2(\pi, \theta_0)}} \right), \quad ...(2.22)
\]

where \( \hat{\pi} \) is given by
\[
\hat{\pi} = \frac{\bar{X}}{\hat{\pi}} \cdot \mu(\theta_0).
\]

Based on \( Z^2 \) we propose a test \( \psi^\prime \) which rejects \( H_0 \) at \( \alpha \) level of significance if \( |Z^2| > z_{1-\alpha/2} \).

The power of the test is given by
\[
\beta_{\psi^\prime}(\pi, \theta) = \sum_{k=0}^{B} \left( 1 - \Phi(B^\prime) + \Phi(A^\prime) \right) P(n_0 = k), \quad ...(2.23)
\]
where
\[
A^\prime = \frac{\mu(\theta_0) - z_{1-\alpha/2} \sqrt{\sigma^2(\hat{\pi}, \theta_0)}}{n \hat{\pi}^2} - \pi \mu(\theta),
\]
\[
B^\prime = \frac{\mu(\theta_0) + z_{1-\alpha/2} \sqrt{\sigma^2(\hat{\pi}, \theta_0)}}{n \hat{\pi}^2} - \pi \mu(\theta)
\]
and \( P(n_0 = k) = \binom{n}{k} (1 - P_0)^{n-k} \cdot P_0 = \left[ 1 - \pi + \frac{a_0}{\pi} \right] \).

Using the tests developed above, we can define two sided asymptotic confidence intervals for \( \theta \) by inverting acceptance regions of the tests appropriately. Below we report the same.

Asymptotic confidence interval for the parameter \( \theta \)

Asymptotic confidence interval for \( \theta \) based on the test \( \psi \) is given by
\[
\left( \hat{\theta} - z_{1-\alpha/2} \sqrt{AV_\theta(\hat{\pi}, \theta)} , \hat{\theta} + z_{1-\alpha/2} \sqrt{AV_\theta(\hat{\pi}, \theta)} \right), \quad ...(2.24)
\]

where, \( AV_\theta(\hat{\pi}, \theta) \) is an estimate of asymptotic variance of \( \hat{\theta} \) and asymptotic confidence interval for \( \theta \) based on the test \( \psi^\prime \) is given by
\[
\left( \hat{\theta} - z_{1-\alpha/2} \sqrt{AV_\theta(\hat{\pi}, \theta)} , \hat{\theta} + z_{1-\alpha/2} \sqrt{AV_\theta(\hat{\pi}, \theta)} \right), \quad ...(2.25)
\]

where \( AV_\theta(\hat{\theta}) \) is an estimate of the asymptotic variance of \( \hat{\theta} \) as given in the eq. (2.13).

Asymptotic confidence interval for \( \theta \) based on the test \( \psi^\prime \) is given by
\[
\left( \frac{X}{\hat{\pi}} - z_{1-\alpha/2} \sqrt{AV_\theta(\hat{\pi}, \theta)}, \frac{X}{\hat{\pi}} + z_{1-\alpha/2} \sqrt{AV_\theta(\hat{\pi}, \theta)} \right), \quad ...(2.26)
\]

DOI: 10.15406/bbij.2016.04.00115
where \( AV_\pi(\hat{x}, \theta) = \frac{\sqrt{n} \left[ \sum_{y=0}^{X} \mu(\theta) \right]}{\sqrt{\sigma^2(\pi, \theta)}} \).

In the following we study inference for zero-inflated Truncated Poisson distribution using results reported in the earlier.

**Zero-Inflated Truncated Poisson Distribution**

Truncated samples from discrete distributions arise in numerous situations where counts of zero are not observed. As an example, consider the distribution of the number of children per family in developing nations, where records are maintained only if there is at least a child in the family. The number of childless families remains unknown. The resulting sample is thus truncated with zero class missing. In continuous distribution, a sample of this type would be described as singly left truncated. In other situations, sample from discrete distributions might be censored on the right.

In this section, we consider zero-inflated truncated Poisson distribution truncated at right at the support point \( 't' \) onwards, where \( 't' \) is known. Moments, maximum likelihood estimators, Fisher information matrix for full and conditional likelihood are provided. We provide three tests for testing the parameter of the ZIPD.

Consider the probability mass function of truncated Poisson distribution (TPD) truncated at the support point \( 't' \) onwards.

The probability mass function of TPD is given by

\[
P(x|t) = \frac{e^{-\theta} \theta^x}{x! A(\theta)} \text{ for } x=0,1,2,...,t
\]

Using this truncated distribution, we define the zero-inflated truncated Poisson distribution truncated at \( 't' \) onwards.

The probability mass function of ZIPD distribution is given by

\[
P(X=x) = \begin{cases} 
(1-\pi) + \pi \frac{A(\theta)}{A(\theta+1)} & \text{for } x=0, \\
\pi \frac{\theta^x}{x! A(\theta)} & \text{for } x=1,2,...,t \text{ and } \theta>0, 0<\pi<1
\end{cases}
\]  

**Estimation of the parameters \( \pi \) and \( \theta \)**

Estimation of the parameters using full likelihood function

Let \( X_1, X_2, ..., X_n \) be a random sample observed from zero-inflated truncated Poisson distribution truncated at \( 't' \) onwards, where \( 't' \) is the point in the support defined in the above probability mass function. Then the likelihood function is given by

\[
L(\theta, \pi, X) = \prod_{i=1}^{n} \left[ 1 + \pi \frac{A(\theta)}{A(\theta+1)} \right]^{1-n_i} \left[ \frac{\pi \theta^x}{x! A(\theta)} \right]^{n_i} \theta > 0
\]

The corresponding log likelihood function is given by

\[
\log L(\theta, \pi, X) = n \log \left( 1 + \pi \frac{A(\theta)}{A(\theta+1)} \right) + \sum_{i=1}^{n} n_i \log \pi + \sum_{i=1}^{n} x_i \log \theta - \sum_{i=1}^{n} \log A(\theta)
\]

To find MLEs of \( \pi \) and \( \theta \), we differentiate the eq. (3.2) with respective \( \pi \) and \( \theta \), and then equating to zero we get

\[
\pi = \frac{\sum_{i=1}^{n} x_i \log \theta - \sum_{i=1}^{n} \log A(\theta)}{n \left( \frac{A(\theta)}{A(\theta+1)} \right)} \]

and

\[
\theta = \frac{\sum_{i=1}^{n} x_i}{\left( \frac{A(\theta)}{A(\theta+1)} \right) A(\theta)}
\]

Substituting \( \pi = \frac{(n-n_i) A(\theta)}{n \left( \frac{A(\theta)}{A(\theta+1)} \right)} \) in the above equation we have

\[
\sum_{i=1}^{n} x_i \left( \frac{A(\theta)}{A(\theta+1)} \right) \left( \frac{(n-n_i) A(\theta)}{n \left( \frac{A(\theta)}{A(\theta+1)} \right) A(\theta)} + \frac{\pi}{1-\pi} \right)
\]

which is non-linear equation in \( \hat{\theta} \). Therefore, we use a numerical technique to solve it.

Using Newton-Raphson iterative formula

\[
\hat{\theta}_{i+1} = \hat{\theta}_i - \frac{h(\hat{\theta}_i)}{h'(\hat{\theta}_i)} \text{ for } i=0,1,2,...,\text{ with suitable initial value of } \theta_0 \text{ we get}
\]

\( \hat{\theta} \). Substituting this value of \( \hat{\theta} \) in eq. (3.3), we get the value of \( \hat{\pi} \).

In the following we find the elements of Fisher information matrix.

Here we have

\[
\frac{\partial \log L}{\partial \pi} = \left( -1 + \frac{1}{A(\theta)} \right) \frac{\sum a_i}{1 - \pi + \frac{\pi}{A(\theta)}} \pi,
\]

\[
\frac{\partial^2 \log L}{\partial \theta^2} = \left( -1 + \frac{1}{A(\theta)} \right) \frac{\sum a_i}{1 - \pi + \frac{\pi}{A(\theta)}} \pi^2,
\]

\[
E \left( \frac{\partial^2 \log L}{\partial \pi^2} \right) = \left( -1 + \frac{1}{A(\theta)} \right) \frac{\sum a_i}{1 - \pi + \frac{\pi}{A(\theta)}} \pi^2
\]

\[
E \left( \frac{\partial^2 \log L}{\partial \theta \partial \pi} \right) = \left( -1 + \frac{1}{A(\theta)} \right) \frac{\sum a_i}{1 - \pi + \frac{\pi}{A(\theta)}} \pi^2.
\]

Further differentiating eq. (3.2) twice with respect to \( \theta \), we get

\[
E \left( \frac{\partial^2 \log L}{\partial \theta^2} \right) = \left( -1 + \frac{1}{A(\theta)} \right) \frac{\sum a_i}{1 - \pi + \frac{\pi}{A(\theta)}} \pi^2
\]

\[
E \left( \frac{\partial^2 \log L}{\partial \theta \partial \pi} \right) = \left( -1 + \frac{1}{A(\theta)} \right) \frac{\sum a_i}{1 - \pi + \frac{\pi}{A(\theta)}} \pi^2.
\]

Therefore,

\[
I_{12} = \frac{n(A(\theta) - 1)}{\pi(A(\theta) - \pi A(\theta) + \pi)}.
\]

Now

\[
\frac{\partial \log L}{\partial \pi} = \left( -1 + \frac{1}{A(\theta)} \right) \frac{\sum a_i}{1 - \pi + \frac{\pi}{A(\theta)}} \pi
\]

\[
\frac{\partial^2 \log L}{\partial \pi \partial \theta} = \left( -1 + \frac{1}{A(\theta)} \right) \frac{\sum a_i}{1 - \pi + \frac{\pi}{A(\theta)}} \pi^2
\]

\[
E \left( \frac{\partial^2 \log L}{\partial \pi \partial \theta} \right) = \left( -1 + \frac{1}{A(\theta)} \right) \frac{\sum a_i}{1 - \pi + \frac{\pi}{A(\theta)}} \pi^2.
\]

The asymptotic variance of \( \hat{\pi} \) and \( \hat{\theta} \) are

\[
AV_{\pi}(\pi, \theta) = I_{11} = \left( I_{11} - \frac{I_{12}}{I_{22}} \right)
\]

\[
AV_{\theta}(\pi, \theta) = I_{12} = \left( I_{12} - \frac{I_{11}}{I_{22}} \right).
\]

1. Conditional likelihood function approach

The conditional likelihood function is given by

\[
\sum a_i x_i \sum a_i \left( A(\theta) \right)^2 \left( A(\theta) - A(\theta)^2 \right)
\]
Inference for Zero Inflated Truncated Power Series Family of Distributions

The corresponding log likelihood function is given by

\[ L'(\theta; x) = \prod_{i=1}^{n} \left( \frac{\theta^{x_i}}{x_i! A(\theta) - 1} \right)^{y_i}, \quad \theta > 0 \]  

... (3.9)

The corresponding log likelihood function is given by

\[ \log L^*(\theta; x) = \sum_{i=1}^{n} x_i \log(\theta) - (n - n_0) \log(A(\theta) - 1) - \sum_{i=1}^{n_0} x_i! \]  

... (3.10)

The corresponding log likelihood function is given by

\[ \log L^*(\theta; x) = \sum_{i=1}^{n} x_i \log(\theta) - (n - n_0) \log(A(\theta) - 1) - \sum_{i=1}^{n_0} x_i! \]  

... (3.11)

Now consider,

\[ \frac{\partial^2 \log L^*}{\partial \theta^2} = \sum_{i=1}^{n} x_i \frac{\sum_{i=1}^{n} \frac{(A(\theta) - 1)A'(\theta) - A'(\theta)^2}{(A(\theta) - 1)^2}}{A'(\theta) - 1} \]

... (3.12)

Therefore, asymptotic variance of \( \hat{\theta} \) is different than the asymptotic variance of estimate of \( \theta \) based on the standard likelihood approach. The same is given by

\[ AV_\theta(\theta) = \left( \frac{(n - n_0)(A'(\theta) - 1)}{A'(\theta) - 1} \right) \left( \frac{A'(\theta)}{\theta} \right) \left( \frac{A'(\theta)(A(\theta) - 1) - A'(\theta)^2}{(A(\theta) - 1)} \right) \]  

... (3.13)

II. Moment estimator of ZITP distribution

Mean = \[ E(X) = \frac{\pi \theta A'(\theta)}{A(\theta)} \]  

... (3.14)

\[ E(X^2) = \frac{\pi \theta A'(\theta) + A'(\theta)}{A(\theta)} \]

\[ Var(X) = \frac{\pi \theta A'(\theta) + A'(\theta) - \frac{\pi \theta A'(\theta)^2}{A(\theta)}}{A(\theta)} = \sigma^2(\pi, \theta) \]  

... (3.15)

\[ \pi = \frac{\pi \theta A'(\theta)}{A(\theta)} \]  

... (3.16)

... (3.17)

Solving eq. (3.16) and eq. (3.17), we get moment estimators of \( \pi \) and \( \theta \).

Tests for the parameter \( \theta \) of ZITP distribution

Suppose we want to test \( H_0: \theta = \theta_0 \) vs \( H_1: \theta \neq \theta_0 \) (assuming \( \pi \) is unknown) [4]

Test based on \( \hat{\theta} \)

\[ Z_4 = \frac{\hat{\theta} - \theta_0}{\sqrt{AV_\theta(\hat{\theta})}} \]  

... (3.18)

where \( AV_\theta(\hat{\theta}) \) is defined in eq. (3.8). The test \( \psi_4 \) rejects \( H_0 \) if \( Z_4 \leq z_{\alpha/2} \).

Test based on \( \hat{\theta} \)

The test statistic here is \( Z_4 = \frac{\hat{\theta} - \theta_0}{\sqrt{AV_\theta(\hat{\theta})}} \)...

... (3.19)

Where, \( AV_\theta(\theta) \) is as defined in eq. (3.13). The test \( \psi_5 \) rejects \( H_0 \) if \( Z_4 \geq z_{1-\alpha/2} \).

I. Test based on sample mean

The test statistic

\[ Z_4 = \frac{\sqrt{n} \left( \frac{\pi}{\theta_0} - \tilde{\theta}_0 \right)}{\sqrt{\frac{n}{\theta_0^2} AV_\theta(\tilde{\theta}_0)}} \]  

... (3.20)

where \( \tilde{\theta}_0 = \frac{EX_\theta(\tilde{\theta}_0)}{\theta_0 A'(\theta_0)} \)

Power of the test is given by

\[ P(n_0 = k) = \sum_{k=0}^{n} \left( 1 - \Phi(\tilde{\theta}_4) \right) P(n_0 = k) \]

\[ \tilde{\theta}_4 = \frac{\theta_0 - z_{1-\alpha/2}}{\sqrt{z_0^{-2} AV_\theta(\tilde{\theta}_0)}} \]

\[ \tilde{\theta}_4 = \frac{\theta_0 - z_{1-\alpha/2}}{\sqrt{z_0^{-2} AV_\theta(\tilde{\theta}_0)}} \]  

... (3.21)

Asymptotic confidence interval for the parameter \( \theta \)

Asymptotic confidence interval for \( \theta \) based on the test \( \psi_4 \) is given by

\[ (\hat{\theta} - z_{\alpha/2} \sqrt{AV_\theta(\hat{\theta})}, \hat{\theta} + z_{1-\alpha/2} \sqrt{AV_\theta(\hat{\theta})}) \]

... (3.21)
Inference for Zero Inflated Truncated Power Series Family of Distributions

where, \( AV(\hat{\theta}, \hat{\theta}) \) is an estimate of asymptotic variance of \( \hat{\theta} \) and asymptotic confidence interval for \( \theta \) based on the test \( \psi_5 \) is given by

\[
(\hat{\theta} - z_{1-\alpha/2} \sqrt{AV(\hat{\theta})}, \hat{\theta} + z_{1-\alpha/2} \sqrt{AV(\hat{\theta})}) \quad \ldots (3.22)
\]

where \( AV(\hat{\theta}) \) is an estimate of the asymptotic variance of \( \hat{\theta} \) as given in the eq. (3.13).

Asymptotic confidence interval for \( \theta \) based on the test \( \psi_6 \) is given by

\[
\left( \frac{X}{\hat{\theta} - z_{1-\alpha/2} \sqrt{AV_\pi(\hat{\theta}, \hat{\theta})}}, \frac{X}{\hat{\theta} + z_{1-\alpha/2} \sqrt{AV_\pi(\hat{\theta}, \hat{\theta})}} \right) \quad \ldots (3.23)
\]

where \( AV_\pi(\hat{\theta}, \hat{\theta}) = \frac{\sqrt{n}}{\sigma^2(\pi, \theta)} \).

Simulation Study

A simulation study is carried out to investigate the power of the two tests proposed in section 3.2. We generate 10000 samples of sizes 100 and 200 for different values of \( \pi, \theta \) and truncation point \( t \). Based on generated sample, the test statistics were calculated. Percentage of times the test statistics exceeds \( Z_{1-\alpha/2} \) is computed, which is an estimate of power of the respective test. R programme is developed to find power of the test. The results for the case of \( \theta = 2 \) and \( 4, \pi = 0.3, 0.4, 0.5, 0.6, 0.7, \alpha = 0.05 \) and truncation point \( t = 7 \) and \( 9 \) are presented in the Table 1 & Table 2.

From the simulation study reported in Table 1 & Table 2, we observe that

I. The test based on full likelihood approach is better than the one based on conditional likelihood approach when \( \theta \) is small. For large \( \theta \), both the tests are equally good.

II. Probability of Type I error of the former test is more than that of later.

III. Since for large values of \( \theta \) both the tests are equally good. We recommend the use of conditional likelihood approach, when \( \theta \) is large, from the computational point of view.

IV. If \( \theta \) is large, proportion of zeros corresponding the Poisson distribution are relatively low. Hence these zeros can be ignored while making inference about \( \theta \). However, for smaller values of \( \theta \), such ignorance will have effect on inference of \( \theta \).

### Table 1: Power (in %) of the test \( \psi_4 \) and \( \psi_5 \) for \( \theta = 2, t = 7, n = 100 \) and \( 200, \alpha = 0.05 \)

**Illustrative Example**

Let us consider the data of Traffic Accident Research given by Kuan et al. [5].

The data from the department of motor vehicles master driver license file

<table>
<thead>
<tr>
<th>Traffic accidents 0</th>
<th>1</th>
<th>2</th>
<th>≥ 3</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number of drivers</td>
<td>4499</td>
<td>766</td>
<td>136</td>
</tr>
</tbody>
</table>

From the data we see that there is excess number of zero counts and the frequency of X is greater than or equal to 3 is 21. Generally such data is modeled by Poisson distribution. But Poisson distribution does not fit well for this data. We fit the above data for ZIPD. In ZIPD there are two parameters $\pi$ and $\theta$. In this problem $n_z = 4499$, $n = 5422$ and estimated values of $\hat{\pi} = 0.5583$ and $\hat{\theta} = 0.3637$. Using these values we fit the ZIPD for the above data. The calculated Chi-square value is 0.4043 and table value of $\chi^2(1, 0.05)$ is 3.841459 and the P-value is 0.5249.

Same data is fitted to ZITPD truncated at 4 and above. The parameters are $\hat{\pi} = 0.5582$ and $\hat{\theta} = 0.3646$. The calculated Chi-square value is 0.4018 and table value of $\chi^2(1, 0.05)$ is 3.8415 and the P-value is 0.5262. If the same data is fitted to ZITPD truncated at 5 and above. The parameters are $\hat{\pi} = 0.5583$ and $\hat{\theta} = 0.3638$. The calculated Chi-square value is 0.4012 and table value of $\chi^2(1, 0.05)$ is 3.8415 and the P-value is 0.5265. Here we prefer ZITPD to model the data.
