Lymphocytic Meningitis, A Rare Feature of Hashimoto’S Thyroiditis: A Case Report

Introduction

Hashimoto’s thyroiditis (HT) is a specific autoimmune disease. Transient hyperthyroidism is observed in 5 to 10% of the patients [1-3]. The diagnosis is often made when hypothyroidism is established. Several neurological features were described in literature [1,4]. Nonetheless, aseptic and lymphocytic meningitis is uncommon [4]. We report an unusual case of a woman with concomitant lymphocytic meningitis and HT.

Case Report

A previously healthy 32-year-old woman was admitted to hospital with fever and headache. Her previous family and personal history was unremarkable. She had a 3 days history of headache, dizziness, nausea and vomiting. She also complained about photophobia and sonophobia.

Physical examination revealed fever at 38.5°C, heart beat rate at 88 per minute, blood pressure at 100/70 mmHg, painless thyroid goiter. Neurological examination showed a meningism with no deficits.

In laboratory, full blood count, C reactive protein, urea, creatinine, electrolytes, liver function tests were normal. Thyroid function tests revealed a hyperthyroid state with reduced serum levels of thyroid-stimulating hormone (TSH 0.001mIU/ml; normal 0.40-4.0mIU/ml) and increased free T4 levels (35pmol/L; normal 10.3-24.4pmol/L).

Furthermore, Lumbar puncture revealed a cell count of 190/mm³ cellle (mostly lymphocytes: 90%), low glucose and increased protein levels (750 mg/dl). Neurological examination showed a meningism with no deficits.

In laboratory, full blood count, C reactive protein, urea, creatinine, electrolytes, liver function tests were normal. Thyroid function tests revealed a hyperthyroid state with reduced serum levels of thyroid-stimulating hormone (TSH 0.001mIU/ml; normal 0.40-4.0mIU/ml) and increased free T4 levels (35pmol/L; normal 10.3-24.4pmol/L).

The diagnosis of HT associated to a lymphocytic meningitis was made. The patient was treated with Thiamazole (20mg daily) and beta blocker (40mg daily). Her neurological features improved within few days and she was discharged. Two years later, neurological relapse did not occur.

Discussion

HT is the most common thyroid disease [1,2]. It is more 8 times more frequent in women than men [1,2]. Hashimoto’s encephalopathy is a scarce syndrome associated with HT. The first case diagnosed with Hashimoto’s encephalopathy was reported in 1966 [5,6]. The clinical findings are various ranging from behavior changes, cognitive impairment, seizures, pyramidal syndrome, involuntary movements, confusion, stroke events, memory loss, coma and psychosis [6]. Our patient has none of these neurological manifestations. She presented with HT associated to a lymphocytic meningitis. In fact, high protein levels are found in up to 85% of patients diagnosed with an Hashimoto’s encephalopathy [4,6-8].

A antithyroid peroxidase antibody is the most found antibody [8]. Besides, abnormal levels of thyroid antibodies can be found in cerebrospinal fluid in case of Hashimoto’s encephalopathy [6,10]. In deed, High fever and hyperthyroidism made it difficult to distinguish this condition from viral encephalitis or thyroid storm, like in our case. In the literature, only one case was reported describing a patient with febrile Hashimoto’s encephalopathy and thyrotoxicosis [9].

Hashimoto’s encephalopathy responds well to glucocorticoids and other immunosuppressive drugs [4,6,10,11].

Neurological and psychiatric features associated to hyperthyroidism usually improves when the disease is rapidly...
controlled. A late diagnosis or inadequate management of the disease can lead to irreversible psychiatric and neurological sequelae [10,11]. Our patient responded well only to antithyroid drug and had no relapse of meningitis within 2 years.

To our knowledge, we reported the first case of febrile lymphocytic meningitis associated with HT. Therefore, we should screen antithyroid antibodies in cases of meningoencephalopathy. HT may be thereby, misdiagnosed and late treated and should be cautiously investigated.
