Study of chemical properties and skin tolerance activity of essential oils extracted from *Rosmarinus Officinalis* and *Populusalba*

**Abstract**

There are many plants which were the subject of recent research in the fields pharmaceutical, cosmetic and agroalimentary because of their chemical composition and their several therapeutic activities. Among these plants, the species of *Rosmarinus officinalis* (rosemary) and *Populus alba* (white poplar) the present study aims to examine the yield and chemical properties of essential oil of rosemary and white poplar. Then, the test of skin tolerance of essential oil was conducted by the measuring of primary irritation index. The results of chemical analysis reveal that the essential oils of the both plants are of acceptable quality. In other hand, the essential oil of *Rosmarinus officinalis* is non-irritating to the skin while the essential oil of *Populus alba* is slightly irritating. This study is essential to ensure the safety of people in contact with substances in pharmaceutical applications.

**Keywords:** essential oils, populus alba, rosmarinus officinalis, irritation

**Introduction**

For several years, the man who lives side by side with the plants is accustomed to consume for their medicinal and nutritional properties. Natural products are of great interest for the various sectors such as cosmetics, pharmaceuticals, food and industry. Currently, the World Health Organization (WHO) estimates that about 80% of people use traditional herbal preparations by lack of access to prescription drugs but also because the plants were able to demonstrate effectiveness. In addition, side effects induced by the drugs concerned users who turn to less aggressive care for the body. Indeed, these plants are often characterized by the biosynthesis of odorous molecules which are called "essential oils" (EO) long known for their therapeutic activities in folk medicine. These bioactive molecules were used given their therapeutic properties in the treatment of several diseases affecting human health. Our work aims to examine the yield and chemical properties of essential oil of rosemary and white poplar. Then, the test of skin tolerance of both essential oils was conducted by the measuring of primary irritation index. This work was carried out at the laboratory of the University of Mascara, beginning the month of May 2014.

**Materials and methods**

**Plant material**

It was constituted of aerial parts (leaves and flowers) of the two plant species, *Rosmarinus officinalis* and *Populusalba*. The plants were collected and were identified in the Mascara region during the month of May 2014.

**The experimental animal**

The Wistar rats used in these experiments were provided by the laboratory of the University of Mascara. Animals were housed at the cage, with water and food *Ad libitum*, and the animal room temperature was kept at constant temperature of 20±1°C on a 12-hour light/12-hour dark cycle. Adequate measures were taken to minimize pain or discomfort of the animals, and all experimental procedures were performed in accordance with the ethical guidelines of the Organization for Economic Cooperation and Development (OECD).

**The physicochemical analyses**

a. **Water content:** The method used was the evaporative drying method.

b. **Ash content:** The method used by the calcinations mineralization method.

** Extraction of essential oils**

The extraction of essential oils from two plants (*Rosmarinus officinalis* and *Populusalba*) was conducted in the laboratories of the University of Mascara. The extraction of essential oils was carried out by hydro distillation in a Clevenger apparatus.100g of leaves and flowers of each plant was boiled. When the temperature stabilizes, we begin to collect the distillate in an Erlenmeyer. We add about 18g of sodium chloride (NaCl) to the distillate. We stir until dissolved, then it was placed in a separating funnel and we achieve three successive washes (10, 10, 20ml) of cyclohexane. After agitation, the organic phase was recovered. The product was dried with a little an hydrousodium sulfate. Then we make a concentration by rotary evaporator to obtain the essential oil. The essential oil obtained was stored at +4°C after the calculation of the yield of extraction.

**Organoleptic characters**

According to AFNOR NF ISO 280: 1999, essential oils must respond to analytical characteristics that are established by international committees of experts. To know the quality of the EO of *R. Officinalis* (Rosemary) and *P. Alba* (white poplar), standard organoleptic tests like color and odor were performed.

a. **Chemical indexes:**

b. **pH:** This measurement was taken using a pH meter.
Study of chemical properties and skin tolerance activity of essential oils extracted from Rosmarinus Officinalis and Populus alba (NF T 75 103, 1982) The acid expresses the number of milligrams of potassium hydroxide (KOH) required to neutralize the free acids contained in one gram of essential oil. 2g of essential oil was added to 5ml of ethanol 95% and 5 drops of phenolphthalein at 0.2%. The solution was neutralized by the solution of KOH (0.1mol / l) until a pink color. The volume of the solution of KOH was denoted. The calculation of AI was given by the formula (1):

\[ AI = \frac{5.61 \times V}{M} \] .......................... (1)

5.61: Corresponds to 0.1 mol / L KOH

M: mass in grams of the essential oil

V: Volume in millilitres of ethanol solution of KOH (0.1mol / l) used for titration.

Ester index: (NF T 75 104, 1982) The ester value is the number of milligrams of KOH needed to neutralize the free acids by hydrolysis of esters contained in one gram of essential oil. 2g of essential oil was added to 25ml of ethanol solution of KOH (0.5mol / l). It adapts the condenser and placed the ball on the heating mantle and allowed to heat for one hour. Then, the solution was added to 20ml of distilled water and 5 drops of 0.2% PP. The excess of KOH solution was titrated with hydrochloric acid 0.5mol / l. A blank test was carried out under the same conditions and with the same reagents. The calculation of EI was given by the formula (2):

\[ EI = \frac{(28.05 \times (V_e - V_b))}{M} - IA \] .......................... (2)

28.05g / l: corresponding to 0.5mol / L KOH.

M: mass in grams of the essential oil

V_e: Volume in ml of the HCl solution (0.5mol / l) used for the blank.

V_b: volume in ml of the HCl solution (0.5mol / l) used to determine the EI of the EO.

Skin tolerance test (PI): The skin tolerance test aims to predict from the knowledge of the toxicity on a living organism, the toxicological risk in humans. The index of primary skin irritation (PI) of our extracts was determined by official method published in the Official Journal of the French Republicon 21February 1982. The method was based on the observation of skin reactions caused by the applying of principle extract.9

Protocol

The method was performed on 6 Wistar rats of body weight between 280-350g. The back and sides were shaved to clear an area of approximately 5cmx5cm; operate with caution so as to avoid irritation. Perform the right of the vertebral axis, using as sterile scalpel blade, three parallel scarifications over a length of about 2.5cm, spaced approximately 0.5cm. Apply the product on the skin (scarified areas and not scarified) at 0.5g. Place the protective compress. Remove the band age twenty-four hours after the applying. The readings were to collectery thema and edemain numerical scale of DRAIZE. To calculate the index of skin irritation(PI), we add the figures recorded for erythema and edema at each reading time (24 and 72 hours after application) on the six areas scarified and six un scarified and then calculate the average of results observed to be classified according to the scale previously cited (3):

\[ PI = (edema + erythema)_scarified + (edema + erythema)_unscarified / 24 \]...(3)

With: 24=number of rats (6)xnumber of tested areas (intact and scarified=2) x number of type of irritation (erythema and edema=2).

The rating system used to generate the observed phenomena by calculating an index of primary skin irritation (PI) to classify the product in 4 categories:

- Action non irritating, PI less than 0.5: PI<0.5
- Action slightly irritating, PI between 0.5 to 2: 0.5< PI<2
- Action moderately irritating, PI between 2and 5: 2< PI<5
- Severely irritating Action, PI between 5 and 8: 5< PI<8

Statistical analysis

The values were expressed as mean ± standard deviation (mean ± SD). The results of the different tests were analyzed by ANOVA single factor for multiple comparisons. The P values less than 0.05 (p<0.05) were considered statistically significant.

Results and discussion

The physicochemical analyzes of the two plants

A. Water and Ash content: Fresh plants were rich in water and contain from 60 to 80% water.10 We used the weight method for determining the water content in the leaves of our plants. It is the determination of the mass loss by drying in an oven. The water content of our samples was of the order of 67.6 ± 0.8% for rosemary and 73.4± 0.5% for the white poplar (Figure 1). Albu and colleagues11 found water content of 40% in the fresh leaves of rosemary; this content differed remarkably with our results. We notice, however, that the two plants showed slightly difference in ash content (3.2±0.5% for rosemary and 2.8±0.3% for the white poplar). Variations encountered in water content and ash content of our samples compared to some earlier work may be due to some environmental factors, age of the plant, the period of the growing season, or even genetic factors.12

Figure 1 The water and ash content of the both plants.
Analysis of essential oils

Extraction yields

The essential oil content, obtained from the aerial parts (leaves + flowers) was 1.29% for the Rosemary and 0.9% for white poplar. The yields of essential oils from two species were widely variable (Table 1). The yield of essential oil of Rosmarinus officinalis was higher than that quoted by Atik Bekkara et al.4 and those of Rouabeh13 where the quantities obtained by the set two works are respectively 0.8% and 0.9%. Indeed, the extraction yield, as the quality of EO, is influenced by the type of soil on which the plant is grown, the material used, the cleanliness of the equipment, the operating pressure, regularity the heating, the cooling of the distillate, method and distillation time.14

Organoleptic characters

It was through the organoleptic properties (appearance, color, smells) that it was possible to define that oil was of adequate quality. After comparison with the standard AFNOR method, the organoleptic properties of essential oils obtained from the two species suggest an essential oil of very good quality. For R. officinalis, the EO has an oily liquid aspect, yellow with a powerful scent of rosemary flowers. Meanwhile the species P. alba, the EO has an oily liquid aspect, pale yellow.

Chemical indexes of essential oils

The values of chemical indexes were collected in Table 2.

Test of skin tolerance (PI)

The evaluation of skin irritation potential was essential to ensure the safety of people in contact with substances in pharmaceutical applications.15 Based on the results, the index of primary skin irritation of R. officinalis essential oil was equal to 0.45 while that of the essential oil of P. Alba was equal to 0.66. According to numerical Draize scale, it was concluded that the essential oil of R. officinalis was non-irritating to the skin (PI=0.5), while the essential oil of P. Alba was slightly irritating (0.5<PI<2). From the results obtained, the observed phenomena were only erythema with a varying degree but a decrease was noted after 72 hours. While edema were totally absent in rats treated with the essential oil of R. officinalis but for the essential oil of P. Alba, a slight appearance of edema during 24 h will be completely disappeared after 72 hours. The appearance of erythema in a few rats can due to penetration of the constituents of the oil in the epidermis.19 Thus, the appearance was quite noticeable on scarified flanks, which may be due to the scarringific, which reaches the dermis. Some factors can affect the erythema phenomena such as rats friction between them during the period of accommodation and even hypersensitivity rats with oil constituents.20 Evaluation of skin irritation potential was essential to ensure the safety of people in contact with substances in pharmaceutical applications.

Conclusion

The results of chemical analysis reveal that the essential oils of the both plants were of acceptable quality. In other hand, the skin tolerance test on rats has allowed us to classify our essential oil of rosemary as non-irritating (PI=0.45), while that based on white poplar was seen as a product to slightly irritating action to the skin (PI= 0.66).
