The renin angiotensin system in liver and lung: impact and therapeutic potential in organ fibrosis

Abstract

Liver and lung fibrosis are two main organ diseases that are of particular importance in both Egypt and the US. Hepatitis C Virus “HCV” infection and Idiopathic pulmonary fibrosis (IPF) are fibrotic diseases of the liver and lung respectively. The liver and lung are reported in literature to share many immune/inflammatory responses to damage through the lung-liver axis. Most importantly, HCV was shown to enhance the development of IPF and is considered one of the risk factors for IPF. The renin angiotensin system (RAS) plays a critical role in the fibrogenesis and inflammation damage of many organs including liver and lung. The relatively recently identified component of RAS, angiotensin converting enzyme-2 (ACE-2), has shown a promising therapeutic potential in models of liver and pulmonary fibrosis. This article reviews the role of RAS in organ fibrosis with focus on role of ACE-2 in fibrotic diseases of the liver and the lung.

Keywords: renin angiotensin system, idiopathic pulmonary fibrosis, hepatitis c virus, bronchopulmonary dysplasia, angiotensin peptide, lung-liver axis

Introduction

Diseases of liver and lung are of particular importance in both Egypt and the US. Hepatitis C (HCV) and schistosomiasis are major causes of liver fibrosis and cirrhosis in Egypt,1,2 while reported cases of acute viral hepatitis C infection increased more than 2.5 times in the US.3 Interestingly, HCV was shown to enhance the development of idiopathic pulmonary fibrosis (IPF) and is considered one of the risk factors for IPF.4 Additionally, treatment of HCV with alpha interferon was shown to worsen IPF.5-6 These facts support the need for a curative treatment of HCV-induced liver fibrosis and IPF different from currently available interferon-based therapy. Another fibroproliferative disease of the lung is bronchopulmonary dysplasia (BPD). BPD occurs in premature neonates with respiratory distress who require supplemental oxygen in the first days after birth. Occurrence of premature birth continues to rise in the US7 with about 20% of preterm infants diagnosed with BPD.8-9 BPD has become more common among Egyptian infants because of advances in care system.10

Liver fibrosis and cirrhosis in hepatitis C

Liver fibrosis is an increasing problem in the Egyptian population due to the spread of schistosomiasis and chronic hepatitis C.11 Hepatitis C virus (HCV) infection is a major medical challenge affecting around 200 million people worldwide. HCV is a major cause of chronic hepatitis, cirrhosis, and liver cancer occurring in up to 3% of the world’s population. Parenteral exposure to HCV is the major mode of transmission of infection. Once established, infection will persist in up to 85% of individuals with only a minority of patients clearing viremia.12 Egypt has possibly the highest HCV prevalence in the world where 10%-20% of the general population is infected with HCV.13 According to the CDC, liver cirrhosis is the 4th cause of death in Egypt with hepatitis being the 9th cause.14 Direct healthcare costs of HCV-related disease exceed $700 million annually and consume approximately 4.0% of the total health expenditure in Egypt, exemplifying the magnitude of the HCV epidemic in Egypt.15,16

In the US, reported cases of acute viral hepatitis C infection increased more than 2.5 times from 2010-2014. Based on new epidemiologic studies, at least 4.6 million persons are HCV-antibody positive and approximately 3.5 million are currently infected with HCV.3 This makes HCV infection the largest blood-borne viral epidemic in the USA, causing more deaths than HIV, and the leading cause of cirrhosis, liver cancer, liver failure, and deaths from liver disease.17,18 Treatment of HCV patients can prevent cirrhosis, liver failure, hepatocellular carcinoma, liver transplantation, and death, and can cure extra hepatic manifestations, relieve symptoms, and improve quality of life.19,20 This emphasizes the need to develop new treatment approach for HCV patients to prevent and reverse or at least attenuate liver fibrosis and cirrhosis. Most importantly, however, many patients with advanced liver disease and cirrhosis suffer from persistent liver injury even years after HCV cure.21,22

Idiopathic pulmonary fibrosis

Idiopathic pulmonary fibrosis (IPF) is the most commonly encountered interstitial lung disease. The published prevalence of IPF in various countries of the world has ranged from 0.7 per 100,000 in...
Bronchopulmonary dysplasia

Bronchopulmonary Dysplasia (BPD) occurs in premature neonates with respiratory distress who require supplemental oxygen in the first days after birth. BPD is recognized as a chronic lung disease of infancy that presents as a systemic syndrome and is associated with neurodevelopmental deficits, cerebral palsy, cognitive impairments, failure to thrive, cor pulmonale, and pulmonary hypertension. High rates of in utero and perinatal exposure to infection may be causally related to preterm delivery and subsequent lung injury. Over the past 2 decades, the histological presentation of BPD has changed from heterogeneous pulmonary inflammation and fibrosis to uniform arrest of alveolar development and variable interstitial cellularity and/or fibroproliferation.

Occurrence of prematurity birth continues to rise in the US (12-13%), and preterm infants are at high risk for long-term medical impairments, including BPD and chronic lung disease of infancy. Many premature newborns require treatment in a neonatal intensive care unit at an annual national cost that exceeds $4 billion, with estimated overall costs of treating babies with BPD to be $2.4 billion. This amount is second only to the costs for treating asthma and far exceeds the costs for treating cystic fibrosis.

BPD is considered the single costliest complication of hospitalization among preterm infants, with an average cost per discharge of $116,000. Despite many advances in neonatal ventilation techniques, widespread use of surfactant and antenatal corticosteroids, the incidence of BPD has remained the same or even increased slightly.

BPD has become more common among Egyptian infants because of advances in care and changes in the gestational age of premature infants. The lack of uniformity in the diagnostic criteria of BPD may be responsible for some of the reported variation. There is even higher incidence of Respiratory Distress Syndrome (up to 80%) seen in preterm infants with very low birth weight in BPD studies on the Egyptian population because of surfactant delay due to limited healthcare resources. BPD is associated with significant pulmonary and neurodevelopmental sequelae that continue to have health consequences into adulthood. Home oxygen therapy averages 92 days, when required and up to 50% of babies with BPD require readmission to the hospital for lower respiratory tract illness in the first year of life. This necessitates developing new approaches for BPD prevention and treatment.

Liver and lung fibrosis

The liver and lung are reported in literature to share many general responses to damage involving oxidative stress and altered extracellular matrix (ECM) deposition in what is called the lung-liver axis. Additionally, both organs possess resident macrophages that play key roles in mediating the immune-inflammatory response. Idiopathic pulmonary fibrosis (IPF) is a possible autoimmune manifestation of HCV infection. A number of studies have suggested an association between IPF and viruses such as hepatitis C. However, there is still some ambiguity with respect to the association between HCV infection and IPF. The following lines of evidence would provide varying degrees of support for a pathogenic link between HCV infection and IPF. First, there is a higher frequency of HCV markers in IPF patients such as anti-HCV antibodies, increased prevalence of HCV infection and viral replication (13.3% vs. 0.3% in control group), second, there is an increased count of lymphocytes and neutrophils in bronchoalveolar lavage fluid in patients with HCV chronic infection. Third, the frequency of pulmonary fibrosis was higher in patients with cryoglobulinemia related to HCV than in cryoglobulin-negative patients. It is suggested that pulmonary fibrosis in HCV-related cryoglobulinemia is triggered by vascular deposition of circulating HCV-containing immune complexes. Furthermore, sometimes IPF is aggravated or manifest after treatment with alpha interferon, the standard therapy for chronic hepatitis C.

Renin angiotensin system in fibrosis

The renin angiotensin system (RAS) has been traditionally viewed as an endocrine system "Endocrine RAS" playing a significant role in blood pressure regulation. In the endocrine RAS, the kidney produced enzyme renin acts on circulating AGT protein. Renin cleaves AGT to produce a fragment of 10 amino acids known as angiotensin I (Ang I). Ang I is converted by angiotensin-converting enzyme (ACE) to the active octapeptide Ang II that exerts its actions through binding to specific cell surface angiotensin receptors. Two main receptors to Ang II have been identified; AT₁ and AT₂, both belong to superfamilies of seven transmembrane G-protein coupled receptors. The AT₁ receptor mediates all of the classical actions of Ang II (vasodilation, sodium retention, cell growth and proliferation), while AT₂ receptor promotes vasodilation, cell differentiation, inhibition of cell growth and apoptosis and may play a counterbalancing role to the effects of Ang II on AT₁ receptor. The angiotensin converting enzyme 2 (ACE-2) was shown to play a protective role in the fibrogenesis and inflammation of many organs including liver and lung. ACE-2 is a part of the renin angiotensin system (Figure 1). ACE-2 and its product angiotensin 1–7 (Ang I-7) acting on mas oncogene receptor were identified more recently than the previously mentioned components of this system and are thought to have counteracting effects against the adverse actions of these other RAS components. Findings from...
numerous experimental studies have suggested notable protective effects in the cardiovascular system.\textsuperscript{56}

\end{center}

\textbf{Figure 1} Renin Angiotensin System (RAS).

More recently, “Local RAS” has been identified in variety of tissues such as heart, kidney, liver, lung, brain, pancreas and adipose tissue, where RAS components expression has been detected.\textsuperscript{57,58} Local RAS is involved in injury, inflammatory and fibrogenic diseases of many organs including heart,\textsuperscript{59,60} lung,\textsuperscript{61,62} liver,\textsuperscript{63} pancreas\textsuperscript{64} and kidneys\textsuperscript{65,66} by mechanisms independent of the blood-derived RAS.

**Angiotensin converting enzyme-2 (ACE-2) in fibrosis**

ACE-2 and its product Ang 1-7 were shown to play a protective role in experimental models of fibrosis. In cardiac fibrosis, ACE-2 expression was shown to be protective against angiotensin II-induced and hypertension-induced cardiac fibrosis.\textsuperscript{67} In liver fibrosis, both Ang 1-7 and ACE-2 provide protection against the development of liver injury and progression to cirrhosis.\textsuperscript{68} In experimental acute lung injury, ACE-2 also has protective effect associated with reduced levels of Ang II. Earlier studies of knockout mice have shown a clear protective effect of ACE-2 on experimental acute lung injury in response to acid aspiration or sepsis; the protective effect of ACE-2 was associated with reduced levels of Ang II after experimental lung injury.\textsuperscript{69} A study on rat brain astrocytes showed that Ang II down-regulates ACE-2 mRNA through angiotensin receptor I in a positive feed-forward system that favors Ang II – mediated responses.\textsuperscript{69} In the lung models of fibrosis, ACE-2 was shown to regulate alveolar epithelial cell survival by balancing the proapoptoticAng II and its antiapoptotic degradation product Ang 1-7 through its receptor “mas”.\textsuperscript{70}

**ACE-2 and pulmonary fibrosis**

Similar to liver disease, ACE-2 has been shown to play an established protective role in lung disease through effects mediated by Mas oncogene, the ACE-2 peptide product ANG1-7 receptor.\textsuperscript{54,71-73} Previous studies from our lab and other groups suggest that ACE-2 is down-regulated in fibrotic conditions of the adult and neonatal human lung\textsuperscript{64,73,74} via Mas receptor mechanisms.\textsuperscript{75} Data from our lab was first to discover the significant decrease of ACE-2 in the human IPF lung and identify the protective effects of ACE-2 in the IPF disease.\textsuperscript{76} We also demonstrated that ACE-2 regulates alveolar epithelial cell survival by balancing the proapoptotic Ang II and its antiapoptotic degradation product Ang 1-7 through the Ang 1-7 action on its receptor “mas”.\textsuperscript{70}

The alveolar epithelial type II cells are considered lung alveolar “stem cells”.\textsuperscript{77,78} They represent a major source of ACE-2 in the adult lung, are normally quiescent but actively proliferate in lung fibrosis due to lung injury and downregulate this protective enzyme. In our studies we found that in lung biopsy specimens obtained from IPF patients, immunoreactive ACE-2 was absent in alveolar epithelia that were positive for proliferation markers but was robustly expressed in alveolar epithelia devoid of proliferation markers. This explained the loss of ACE-2 in lung fibrosis and demonstrated cell cycle-dependent regulation of this protective enzyme.\textsuperscript{79}

**ACE-2 and bronchopulmonary dysplasia**

Bronchopulmonary dysplasia (BPD) is recognized as a chronic lung disease of infancy that presents as a systemic syndrome and can be associated with neurodevelopmental deficits, cognitive impairments, failure to thrive, pulmonary hypertension and cor pulmonale.\textsuperscript{71} Supplemental oxygen, which is frequently used in the treatment of pulmonary insufficiency in premature infants, has been implicated in the development of BPD.\textsuperscript{72,73} In adult animal models of acute lung injury,\textsuperscript{79,80} ACE-2 was shown to inhibit lung edema formation and inflammation as well as fibrogenesis. However, little is known about the role of ACE-2 in neonatal models of BPD. Our research group showed that ACE-2 is expressed in fetal human lung fibroblasts but is significantly decreased by hyperoxic gas lung injury,\textsuperscript{81} an effect reversed when hyperoxia preceded by hypoxia.\textsuperscript{82} Furthermore, Wagenaar et al.\textsuperscript{75} showed that Mas receptor agonists reduce inflammation of the oxygen-induced lung injury in rats.\textsuperscript{75}

Chorioamnionitis and mechanical ventilation are also associated with bronchopulmonary dysplasia (BPD) in preterm infants.\textsuperscript{83,84} A study by Hillman et al.\textsuperscript{85} on neonatal lamb model of chorioamnionitis and infection showed altered ratio of ACE-1 to ACE-2.\textsuperscript{85} Although studied in adults, a recent pilot clinical trial of GSK2586881, a recombinant form of human angiotensin-converting enzyme 2 (rhACE-2) was performed in adults with acute respiratory distress syndrome. As a result of treatment there was a trend for a decrease in interleukin-6 concentrations in rhACE-2-treated subjects compared with placebo.\textsuperscript{86} This shows potential use of ACE2 as a therapeutic for neonates as well.

**Conclusion**

Fibrotic diseases of the liver and the lung are of great healthcare concern and economic importance in both the US and Egypt. HCV-induced liver fibrosis, IPF, and BPD are fibrotic diseases of the liver and the lung in which a role for the RAS has been established. The
increasing rate and incidence of HCV in both the US and Egypt necessitates exploring new treatment options for liver fibrosis. HCV is also considered a risk factor for IPF, the most common form of interstitial lung disease with no definite cure so far. This also mandates novel therapeutics exploration for IPF. Both the liver and lung share common responses to damage leading to disruption in the ECM and leading to organ fibrosis. The local RAS contains many molecules. The ACE/Ang II/AT1 axis of the system plays role in the development of fibrotic diseases, while the other counter components, ACE-2/Ang1-7/Mas axis, have shown potential protective effects in organ fibrosis. Treatment of liver and lung fibrosis by stimulating this protective arm of RAS would offer new therapeutic options.

Authors are shedding the light on the connection between and the importance of lung and liver fibrotic diseases. Futures studies are planned by authors to further understand role of RAS in Lung and Liver injury and suggest that RAS modification by using e.g. ACE-2 might be a potential therapy to prevent/attenuate Lung and liver fibrosis/disease.
