Socio-Cultural Practices and Beliefs Influencing Infant and Young Child Feeding in Lubao Sub-Location Kakamega County

Abstract

Background: Optimal feeding practices for children aged below 24 months are important for the growth and Development and also for reducing childhood mortality and morbidity for this critical group. Social cultural beliefs and practices dictate behavior and practices of the people hence they influence feeding practices.

Objective: The purpose of this study was to find out how the socio-cultural beliefs and practices influence the feeding practices for children aged below 24 months in Lubao sub location in Kakamega County.

Methods: This study was a cross-section study conducted between from January to March, 2016 in the rural western region amongst primary care givers of children aged below 2 years. Random sampling technique was utilized to select the target sample and from a target population of 1000, a sample of 166 was calculated. Structured questionnaires were used to collect data on socio-cultural beliefs influencing the feeding practices.

Findings: The level of education and knowledge of forbidden foods had a positive correlation (rho-0.328) at (p>0.01). Approximately, 20(20%) reported foods recommended for the infants and young children while 80(80%) reported no specific foods recommended. Reasons associated with the recommended foods were; 4(20%) culture, 9(45%) lack of knowledge, 7(35%) due to other reasons.

Conclusion: Cultural beliefs and taboos i.e. food taboos/restriction, beliefs associated with certain foods, have a strong influence on infant feeding and undermines optimal infant feeding practices; breastfeeding and complementary feeding.

Keywords: Socio-cultural practices; Beliefs; Infant and young child feeding

Background

Globally, only a third of breastfed infants 6-23 months of age meet the criteria of dietary diversity and feeding frequency that are appropriate for their age [1]. Infant and young child feeding practices in 33 countries located in Africa, Asia, Latin America, and the Caribbean showed high rates of noncompliance with infant and young child feeding (IYCF) recommendations International Baby Food Action Network [2]. In Kenya, despite the adoption of a set of high impact IYCF policies and guidelines, only 39% of all children age 6-23 months are fed in accordance with the recommendations. In Kenya, 61 percent of children less than six months are exclusively breastfed. More than half of children in Kenya are still breastfeeding at age 20-23 months (51 percent). The proportion of breastfed children declines with age; breastfeeding is nearly universal in a child’s first month of life, but the proportion breastfed drops to 61 percent by the time a child is 18-23 months. Under nutrition in the 6-24 month age group in developing countries is a direct consequence of caregiver complementary feeding practices Kikafunda et al. [3] in turn resulting in significant childhood morbidity and mortality since the surviving children have increased susceptibility to and have compromised physical growth, impaired cognitive development and reduced lifetime earnings [4]. Evidence shows that decline in length-for-age mainly occurs during the complementary feeding period, between 6 and 24 months of age [5]. Indeed, poor complementary feeding has been identified as a risk factor associated directly with stunting [6].

About 220 000 child lives could be saved every year with promotion of optimal breastfeeding and appropriate complementary feeding WHO [1]. Interventions promoting optimal complementary feeding could prevent up to 6% of deaths in countries with high mortality rates [7,8]. The complementary feeding period represents a significant window of opportunity...
when nutrition has the greatest effect on child health, growth and development [9,10]. There exists a significant gap in explaining why in spite of the adoption of high impact IYCF policies and guidelines in Kenya, there is still low compliance to the recommended practice. The gravity of nutritional outcomes during this period also underpins the urgency for contextualized evidence-based interventions to prevent malnutrition in these children by targeting and improving complementary feeding practice. The description of the social cultural belief and practices on breastfeeding and complementary feeding practice will be an important step in facilitating the formulation of interventions to address situation. The complementary feeding period and associated practices play a significant role in health and development outcomes of infants and young children [2,11]. This period presents an opportunity within which appropriate interventions can result in tangible gains [9] as infant and young child feeding is a critical component of child survival and promotion of healthy growth and development. Taking into consideration the multifaceted and dynamic nature of infant and child feeding within the first two years and the scale of the study, four of the recently updated WHO IYCF core indicators were used as a guideline in describing complementary feeding practice. This was to facilitate the achievement of the study’s aim of gathering and synthesizing information on the social cultural belief of complementary feeding practice among infants and young children aged 6-24 months. The study intended to identify specific factors influencing complementary feeding practices thus highlight the factors promoting ideal and those leading to suboptimal infant feeding practices. Knowledge of feeding practices, their correlates and utilization of the modified WHO IYCF indicators will facilitate better monitoring of trends in the feeding practices and the design of locally appropriate interventions to increase the recommended feeding practices and thereby contribute to reducing malnutrition in the significant infant and young child population of. Overall the study will inform policy makers of appropriate evidence based interventions from the local level to the level of policy making to ensure optimal outcomes for this critical age group.

Methodology

This study was a cross-sectional study conducted between from January to March, 2016 in the rural western region amongst primary care givers of children aged below 2 years. The rural region was purposively sampled due to the high impact of culture and development of infants and young children [2,11]. 1,515 children were introduced to complementary feeds before 6months of age. A total of 100 participants met the eligibility criteria and were recruited in the study. The sample size, 47 (47%) were exclusively breastfed, while 53(53%) were mixed fed. Reasons for lack of exclusive breastfeeding included, 14(26%) as a result of lack of knowledge, 14(26%) cultural factors, 19(36%) mother’s unavailability, and 5(9%) due to other reasons. Among the breastfed infants and young children, 44(44%) breastfeeding was initiated 30 min after birth, 40(40%) within 1-2 hours, and 16(16%) initiation was done after 2hours and beyond. Reasons for late initiation of breastfeeding included sickness of the mother 10(10%), lack of knowledge 10(10%), culture 17(17%) and lack of breast milk 14(14%). Initiation of breastfeeding correlated positively (rho=0.52=98), but statistically insignificant (p>0.01) with the education level of the caregivers. Colostrum feeding frequencies were as follows; 91% of the study participants were fed on colostrum, and 9% were not. For this 9 not fed on colostrum, 6(67%) was due to cultural factors and 3(33%) was due to lack of knowledge. Among the 100 study participants, 11 (11%), were given prelacteal foods and 89 (89%) did not receive prelacteal feeds. Introduction of these feeds was due to various factors; of the 11 who received prelacteal feeds, 4(36%) was due to culture, 5(46%) was due to lack of breast milk and 2(18%) was due to inadequate knowledge. Place of birth and introduction of prelacteal feeds were correlated both positively (rho=0.264) and highly significantly (p<0.01). Determinants of breastfeeding frequency included; child’s demand 33(33%), mothers availability 57(57%) and other determinants contributed to 10%. Provider of breastfeeding education was as follows; 78(78%) received breastfeeding education from healthcare provider out of which only 37(47%) practiced EBF while 41(53%) did not practice EBF. 5 of the participants received BF education from their relatives but only 3(33%) practiced BF. 7 of the participants who received BF education from their fellow women with children, 3(43%) did EBF while 4(57%) did not exclusively breastfeed. EBF positively correlated with the kind of breastfeeding education provider (rho=0.857) but insignificantly (p=0.01). Among the 100 participants, 47% were introduced to complementary feeds before 6months of age. 13 (25%) of this was due to lack of knowledge, 9(17%) cultural reasons and 22(41%) mothers unavailability and 9(17%) was due to other reasons. 31 of the participants reported forbidden foods for infants and young children and 69 reported there were no forbidden foods. Reasons associated with the forbidden foods were; 17(54%) were culture, lack of knowledge 7(23%) and 7(23%) was due to other reasons. The level of education and knowledge of forbidden foods had a positive correlation (rho=0.328) but insignificant (p>0.01). 20(20%) participants reported that there were foods recommended for the infants and young children while 80(80%) reported no specific foods recommended. Reasons associated with the recommended foods were; 4(20%) culture, 9(45%) lack of knowledge, 7(35%) due to other reasons. The relationship between early CF and recommended foods was positive but insignificant.

Discussion

The results of my study showed that social cultural practices and beliefs influenced feeding of feeding and young children. The social practices that influenced feeding were the demographic.
characteristics that ranged from level of education of care giver, the burden of responsibilities of the care giver. The cultural factors were the beliefs associated with certain foods, food taboos/ restrictions and influence of the cultural custodians on the feeding of infant and young children. The introduction of prelacteal feeds, commonly water added sugar and salt and few using herbal drops significantly led to reduced prevalence of EBF. The prelacteal beliefs were associated with the cultural beliefs evidenced by the statements “opened up the infants intestines” and cleaned the stomach of the dirty contents by inducing vomiting. The cultural custodians especially the child's grandparents had a significant influence prelacteal feeding. Feeding of the prelacteal feeds delayed initiation of breastfeeding within the recommended 30 minutes and this undermined suboptimal breastfeeding. Also maternal factors like lack of breast milk, mothers' sickness and lack of knowledge led to prelacteal feeding. A small percentage of the respondents admitted not feeding their children with colostrum. Customary it was believed that colostrum was “dirty milk” and “waste” from the mother hence should not be fed to infants. Also lack of knowledge lead the mothers not feeding their infants on eggs as it was belief both EBF and CF. This study found a common taboo that most喂养 and also beliefs associated with certain foods influenced optimal infant feeding practices. In this study there was a noticeable practice of late initiation of breastfeeding, this was as a result as cultural beliefs held against colostrum where the colostrum had to be first expressed several times and discarded and this delayed breastfeeding and also prelacteal feeding delayed initiation of breastfeeding. The source of breastfeeding information by the relatives especially the respected members who were cultural custodians influenced EBF as evidenced in the study were some mothers who received breastfeeding information from their relatives did not practice EBF. According to the study the mother's unavailability influenced optimal breastfeeding where due to increased burden of responsibilities the mother had to introduce foods early to due reduced frequency of breastfeeding as a result of lack of time. This undermined the optimal BF practice due to mixed feeding. According to study the prevalence of early introduction of complementary feeds was quiet high, 47%. The reasons linked to the early introduction of feeds ranged from cultural influences, lack of maternal knowledge and increased maternal responsibilities. Increased maternal burden of responsibilities led to early introduction of other foods before 6 months of age as the mothers could not afford time to adequately breastfeed the child. Lack of knowledge about child feeding as explained in perception of “insufficient breast milk” by so many of the respondents led to early introduction of foods.

Various diet restrictions and food taboos imposed on infant feeding and also beliefs associated with certain foods influenced both EBF and CF. This study found a common taboo that most infants and young children were not fed on eggs as it was belief that the eggs made the “tongue heavy” hence would cause the child not be able to talk in the or would delay. This belief compromised appropriate CF as children missed on the nutrients provided by the eggs. Also customs regarding gender and food distribution in the households affected child feeding as care givers reported that men were served the large and better portions of food first before children and women, also there were some parts of meats especially organ meats that could not be eaten by children and women. There was a gap in knowledge as most mothers believed that protein foods like fish were not appropriate for their children. A small number of the respondents reported a local belief of a practice that involved burning a certain kind of fish and a small amount of the ashes were fed to the infant or the young child. This helped soothe the baby to sleep as the baby would adapt the character of the fish which was asleep and it’s dormant most times. Most caregivers had a high preference for feeding their infants on porridge as early as during the first month as many explained that porridge was good to make the child strong, this showed a large gap in child feeding knowledge [20-42].

Conclusion

Several factors that undermine appropriate child feeding have a direct impact on the child’s health, growth and development. The factors ranged from inadequate maternal knowledge, ignorance, socio factors, burdens and patterns of responsibilities, to cultural beliefs and taboos.

Cultural beliefs and taboos i.e. food taboos, restriction, beliefs associated with certain foods, have a strong influence on infant feeding and undermines optimal infant feeding practices; breastfeeding and complementary feeding.

Despite the guidelines and policies put in place to promote EBF and appropriate complementary feeding the prevalence of EBF and appropriate CF is still low due to many factors and one being sociocultural practices and beliefs.
