Assessment of microbiological quality of male patients with infertility at Murtala Muhammad specialist hospital Kano, Nigeria

Abstract

The study was aimed to assess microbiological quality of male patients with infertility at Murtala Muhammad specialist hospital Kano, Nigeria. Two hundred (200) Semen specimens were collected from males with infertility attending the clinic and General out Patient Department of MMSH Kano. The seminal fluids were diluted with sterile saline, centrifuged and cultured on Nutrient agar, Blood agar, Chocolate agar and MacConkey agar then incubated aerobically and in 5% CO₂ at 37°C for 24 hours for the isolation of pathogenic microorganism. Isolates were identified based on Gram’s staining, biochemical tests and API 20E Test. The result shows that out of the 200 samples examined 76 (38%) were found to be infected with a total of seventy six (76) isolates. *Staphylococcus aureus* was found to have the highest occurrence of 31 (40.79%), whereas the least was found to be Mycoplasma species, 1 (1.32%). Other microorganisms encountered include; Coagulase negative *Staphylococcus* species 14 (18.42%), *Escherichia coli* 11 (14.47%), *Klebsiella pneumoniae* 6 (7.89%), *Proteus mirabilis* 5 (6.58%), *Pseudomonas aeruginosa* 3 (3.95%), *Neisseria gonorrhoeae* 2 (2.63%) and Candida species 3 (3.95%). The result also shows that patients within the age range of 30-39 years were most infected with 35 (40.1%) infected out of 93 examined. The highest number of isolated microorganisms was observed in samples with concentration of 0-20 x10⁶/ml. The semen motility rate was reduced significantly in samples with pathogenic microorganisms.

Keywords: infertility, kano, microorganisms, semen analysis

Introduction

Infertility is the inability of a sexually active, non-contraception couple to achieve spontaneous pregnancy in one year. About 15% of couples do not achieve pregnancy within one year and seek medical treatment for infertility.¹ One in eight couples encounters problems in attempting to conceive a first child and one in six when attempting to conceive a subsequent child. Both sexes are more or less equally involved in infertility problem.² Men either alone or along with their female partners, contribute to 40–45% cases of infertility.³ Furthermore, infectious etiology involving bacteria, virus, fungi, and protozoa contribute to 15% of male factor infertility.⁴ Some of the microbes are acquired exogenously or endogenously and they could cause infertility in several ways: by damaging sperm motility, deterioration of spermatogenesis, altering the chemical composition of the seminal fluid by dysfunction of accessory sex glands, or by inducing autoimmune processes due to inflammation.⁵

Microbial infections of the genital tracts or semen are major causes of male infertility.⁶⁻⁷ According to World Health Organization, semen consists of concentrated suspension of spermatozoa and the fluid secreted by the accessory sex organs namely prostate gland, seminal vesicles, bulbourethral glands, and epididymides. The fluid secretion is about 90% of semen volume and dilutes the concentrated epididymal spermatozoa at ejaculation. Since the ejaculate is a mixture of secretions derived from the urogenital tract and the male accessory glands, seminal culture identifies the presence of germs in any section of the seminal tract.⁸

Male urogenital tract infections are one of the most important causes of male infertility worldwide. Askienazy-Elnhar,⁹ reported that genital tract infection and inflammation have been associated to 8–35% of male infertility cases and male accessory sex glands infection is a major risk factor in infertility.¹⁰ Studies have also shown that when the characteristics of semen infected and uninfected were compared, semen with micro-organisms had poor indices of fertility.¹¹ Infertility affecting couples around the World is both a medical as well as social problem particularly in Nigeria.¹² Evidences are being accumulating on the association of asymptomatic bacteriospermia and altered semen quality.¹² There is difference as to the influence of certain microbial infection on male infertility.¹³ Urinary tract infections are common in men and clinicians working with infertility frequently encounter patients with these diseases.¹⁴ More than 90% of male infertility cases is due to either low sperm count (oligospermia), no sperm at all (azoospermia), or poor seminal fluid quality or combination of the two and this claimed to be the increase prevalence of sexually transmitted diseases (STDs) and urogenital infections alarmed since 1992.¹⁵ Previous studies have identified *Staphylococcus aureus*, *E. coli*, *Citrobacter species*, *Klebsiella species*, *Pseudomonas aeruginosa*, *Proteus vulgaris*, and *Proteus mirabilis* with infertility in male partners of infertile couples.⁷,¹⁶ The study was aimed to assess microbiological quality of male patients with infertility at Murtala Muhammad specialist hospital Kano, Nigeria.

Materials and methods

Study area

The study was conducted at Microbiology Department of Murtala Muhammad Specialist Hospital (MMSH), Kano. Kano state is located...
in the North-west Nigeria with coordinates 110 30 N 80 30 E. It shares borders with Kaduna state to the south-west, Bauchi state to the South-East, Jigawa state to the East, Katsina state to the West and Niger republic to the North. It has a total area of 20,131km² (7,777sqm) and population of 11,058,300.16

Study population

A total of 200 samples were collected from male patients who had either primary or secondary infertility cases.

Inclusion criteria for patients

Male patients with any kind of infertility attending MMSH were involved in the study.

Exclusion criteria

a. Male patients who refused to observed at least three days of sexual abstinence prior to the test.
b. Patients who refused to suspend any chemo antibiotic treatment for at least one week prior to sample collection

Ethical clearance

An approval (MOH/off/797/T.I/49) for the study was obtained from Research and Ethic committee Kano state ministry of health. The aim of the study was explained clearly to the clients and informed consent obtained before proceeding to the study.

Determination of sample size

Sample size for the study was determined from a standard formula for the calculation of minimum sample size.17 Sample size was given by the formula:

\[ N = \frac{(Z_{1-a})^2 (p) (1-p)}{d^2} \]

\( N \) = minimum sample size.
\( Z_{1-a} \) = value of standard normal deviate which at 95% confidence interval has found to be 1.96.
\( p \) = the best estimate of prevalence obtained from literature review (12.3%).
\( d \) = difference between the true population rate and sample that can be tolerated, this is the absolute precision (in percentage) on either side of the population.

\[ N = \frac{(1.96)^2 (0.123) (1-0.123)(0.05)^2}{1.96^2} = 165.758 \]

The microbial isolates obtained from seminal fluids analyzed in laboratory are presented in Table 1. The result shows a total of seventy six (76) isolates were obtained, Staphylococcus aureus was found to have the highest occurrence of 31(40.79%), whereas the least was found to be Mycoplasma species, 1(1.32%). Other microorganisms encountered include; Coagulase negative Staphylococcus species 14 (18.42%), Escherichia coli 11(14.47%), Klebsiella pneumoniae 6(7.89%), Proteus mirabilis 5(6.58%), Pseudomonas aeruginosa 3(3.95%), Neisseria gonorrhoeae 2(2.63%) and Candida species 3(3.95%).

Results

Isolation of microorganisms

The microbial isolates obtained from seminal fluids analyzed in laboratory are presented in Table 1. The result shows a total of seventy six (76) isolates were obtained, Staphylococcus aureus was found to have the highest occurrence of 31(40.79%), whereas the least was found to be Mycoplasma species, 1(1.32%). Other microorganisms encountered include; Coagulase negative Staphylococcus species 14 (18.42%), Escherichia coli 11(14.47%), Klebsiella pneumoniae 6(7.89%), Proteus mirabilis 5(6.58%), Pseudomonas aeruginosa 3(3.95%), Neisseria gonorrhoeae 2(2.63%) and Candida species 3(3.95%).

Microbial distribution in relation to age

The distribution of microorganisms in relation to patient’s age is presented in Table 2. From the table, out of the 200 samples examined 76(38%) were found to be infected. The result also shows that patients within the age range of 30-39 years were most infected with 35(40.1%) infected out of 93 examined while those within the age range of 60-69 years were the least with only 1(1.3%) infected out of total of 4 samples.

Distribution of semen parameters in relation to microbial isolates

The distribution of semen parameters among various microorganisms are shown in Table 3. The highest number of isolated microorganisms was observed in samples with concentration of 0-20 x10^6/ml. This was followed by those with concentration of 20-60 x10^6/ml while the least number of microorganisms was observed from samples with concentration >60 x10^6/ml. The table also shows the highest progressive motility been recorded in a few fraction of Bacteriospermic samples while majority shows poor to medium motility. Motility rate was reduced significantly in samples with pathogenic microorganisms.

**Discussion**

The study was aimed to assess microbiological quality of male patients at Murtala Muhammad specialist hospital Kano, Nigeria. The result shows a total of seventy six (76) isolates were obtained, Staphylococcus aureus was found to have the highest occurrence of 31(40.79%), whereas the least was found to be Mycoplasma species, 1(1.32%). The higher prevalence of S. aureus in the study agrees with previous works. Komolafe & Awoniyi reasoned that, the isolation of S. aureus might be associated with body hygiene of the couples involved. Moreover, Charanchi et al. contended that, the higher occurrence of S. aureus in semen of patients with infertility could be attributed to its minimal growth requirements, high resistance to environmental factors and ability to colonize and establish infection. Conversely, the least occurrence of Mycoplasma species in this study disagrees with the work of Domes et al. Staphylococcus species are known opportunistic pathogens which are usually involved in Nosocomial and human urinary infections. Since urinary tract always act as locus of infections for the seminal tract, the heterogeneity of microorganisms encountered are capable of causing classical infections of the urogenital tract and according to Ibadin & Ibeh male urogenital tract infections are one of the most important causes of male infertility worldwide.

Table 2 shows the distribution of microorganisms in relation to patient’s age. From the table, out of the 200 samples examined 76(38%) were found to be infected. The result also shows that patients within the age range of 30-39 years were most infected with 35(40.1%) infected out of 93 examined while those within the age range of 60-69 years were the least with only 1 (1.3%) infected out of total of 4 samples. This is in agreement with the works of Komolafe & Awoniyi where male partners of 20 to 49 years age range were found to be most infected.

affected. This might be due to their involvement in high-risk sexual behaviour or polygamous relationships, or as a result of urogenital infections. This implies that infertility and polymicrobial infections were common among young couples as shown in Table 2. Momoh et al., noted that many who are infected with several pathogens may lack symptoms and signs of infection but presence of polymicrobial infections is one of the reasons adduced for erectile dysfunction. According to Brogden et al., the presence of one microorganism can predispose the host to colonization or infection by another organism there by justifying the recognition of the significance of polymicrobial infections and the major types of microbial community interaction associated with human health and diseases.

The interrelationships of microorganism and semen parameters showed that the highest number of isolated microorganisms was observed in samples with concentration of 0-20x10⁶/ml. This was followed by those with concentration of 20-60x10⁶/ml while the least number of microorganisms was observed from samples with concentration >60x10⁶/ml. The table also shows the highest progressive motility been recorded in samples without pathogenic microorganisms. Motility rate was reduced significantly in samples with pathogenic microorganisms. This implies that the presence of pathogenic microorganisms exerts a negative effect on spermatozoa concentrations which supports earlier observations. S. aureus occur in all ranges to spermatozoa concentrations. This may be related to its success as major human commensal and pathogen, partly due to some strain that have the ability to rapidly develop resistance to several antimicrobial agents. This suggests that these microorganisms are strongly associated with deterioration of semen indices. Similarly, the presence of pathogenic microorganisms in seminal fluid as recorded in this study was associated with decline in total and progressive motility indices when compared with non-pathogenic microorganisms which agrees with Golshani et al. This is suggestive that pathogenic microorganisms. Motility rate was reduced significantly in samples with pathogenic microorganisms. This implies that the presence of pathogenic microorganisms exerts a negative effect on spermatozoa concentrations which supports earlier observations. S. aureus occur in all ranges to spermatozoa concentrations. This is suggestive that pathogenic microorganisms.

Conclusion

In the study Staphylococcus aureus is the most prevalent microbes associated with infertility in male partners of infertile couples and the presence of Escherichia coli might be an indication of poor personal hygiene among couples. The result also shows that patients within the age range of 30-39 years were most infected. The interrelationships of microorganism and semen parameters showed that the highest number of isolated microorganisms was observed in samples with concentration of 0-20x10⁶/ml.
