Plant extracts are the potential inhibitors of α-amylase: a review

Abstract

Diabetes mellitus is a metabolic disorder characterized by chronic hyperglycemia with disturbances of carbohydrate, lipid and protein metabolism resulting from defects in insulin secretion, insulin action or both. Among the various therapeutic approaches to treat diabetes, postprandial hyperglycemia reduction is at most importance. This approach is used to prevent absorption of glucose by the inhibition of enzymes which hydrolyze carbohydrates, such as α-amylase. The α-amylase is one of the main products of secretion of the salivary glands and pancreas, which plays a role in the digestion of starch and glycogen and can be found in microorganisms, plants and higher organisms. α-amylase enzyme catalyzing the initial step in the hydrolysis of starch to the oligosaccharide mixture consisting of maltose, malt triose 6-8 and oligosaccharides containing glucose units both α-1,4 and α-1,6 linkages branched. Here in the present work a review was carried to collectively highlight all those potent α-amylase inhibitors whose sources are plants. These inhibitors possess antioxidant and are the considered strong tools in future treatments of diabetes mellitus as well free from side effects.

Keywords: carbohydrates, diabetes mellitus, hyperglycemia, treatments, hydrolysis, pharmacologically, inhibitors, therapeutic approach, alpha-amylase, medicine

Introduction

Diabetes mellitus is a group of metabolic diseases considered by hyperglycemia resulting from failures in insulin secretion, insulin action or both. It is characterized by hyperglycemia and accompanied by various chronic vascular complications. An estimated 171 million people worldwide have diabetes, which may probably double in 2030 and about 3.2 million deaths each year are attributable to complications of diabetes; six deaths every minute.

Oligosaccharides and disaccharides are decomposed into monosaccharides by Glycosidase and α-amylase. Starch is primarily broken down to oligosaccharides owing to the hydrolytic activity of these enzymes. Like other nutrients, carbohydrates are mostly digested in the small intestine; however, it is the salivary amylase that sets out these enzymes.

The glucosidase enzymes (maltase, lactase and sucrase) secreted by the glands and pancreas, which plays a role in the digestion of starch and glycogen and can be found in microorganisms, plants and higher organisms. α-amylase enzyme catalyzing the initial step in the hydrolysis of starch to the oligosaccharide mixture consisting of maltose, malt triose 6-8 and oligosaccharides containing glucose units both α-1,4 and α-1,6 linkages branched.

Several authors have reviewed the possibility of medicinal plants as inhibitors of α-amylase. It has been reported that around 800 different plant species exhibit anti-diabetic properties relevant to the
treatment of type 2 diabetes. A wide range of principles derived from plants belonging to the compounds, mainly glycosides, alkaloids, hypoglycans, galactomannan gum, polysaccharides, steroids, peptidoglycan, guanidine, glycol peptides and terpenoids, have shown biological action against hyperglycemia. A list of plants reported to have significant inhibitory activity against α-amylase enzyme is shown in (Table 1). L. Syzygium cumini L. (syn: Eugenia jambolana Lam) and Psidium guajava L. are extensively used traditional system of medicine for the treatment of diabetes in India. Aqueous extracts of seeds and P.S. cumingiau java leaves both demonstrate dose-dependent inhibitory effect on α-amylase activity. Extract of S. cumini seeds also drastically diminish blood glucose point in diabetic rats. It was confirmed that the extracts of ethyl acetate, methanol, and hexane from two varieties of Amaranthus caudatus L. Seeds (White and Red Victor Oscar. Oil) showed inhibitory activity of α-amylase (above 80% inhibition rate) by 0.251mg/mL. Extracts buffered various plant species namely Desert date L., Camellia sinensis L. Del., Galega officinalis L., Holarhena floribunda (Don) Durand and Schinz, Khaya senegalensis (Desr.) A. Juss., Melissa officinalis L., Mitragyna inermis (Wild) O. Ktze., Rosmarinus officinalis L., Securidaca long epedunculata Fresen., Tamantis indica L., Taraxacum officinale web. Wiggex., Vaccinium myrtillus L. and were selected for α-amylase activity and showed momentous inhibitory activity (above 45% inhibition rate of 0.2g/ml). The methanol extracts of 41 plants used in traditional medicine in Mongolia have been tested for α-amylase inhibitory properties and significant inhibition of the enzyme was demonstrated by Rhodiola rosea L., Ribesand vacciniumulag in osmopulchellich Turcz L; geranium extracts pretense L, Leonotopodium ochroleucum Beav., Paeonia anomala L., and Penta phylloides fruticosus L. Schwarz illustrate α-amylase inhibitory activity greater than 30%. Loizzo, et al. examined extracts of melathol, hexane and chloroform from nine Lebanon recommended for diabetes traditional medicinal plants. Ayurveda, the traditional system of herbal medicine practiced in India for over thousands of years have reports of anti-diabetic plants with no known side effects apparent. Chloroform extracts six plants Azadirach taicidia A. Jussnamely, S. cumini, Tenuflorum ocimum L., Curry tree (L.) Spreng and traditionally used din Ayurveda with Bougainvillea spectabilis Wild, used as a plant of hypoglycemia in the West Indies and Asia were selected for inhibitory activity of α-amylase Significant inhibition with extracts from O. tenuflorum. Six more Indian medicinal plants were tested for their effect on α-amylase activity between them, Mangifera indica L., Embelia ribes Burm., Phyllanthus mader as patensissinn Linn. Punica granatum L. and showed interesting inhibitory activity of α-amylase. The enzyme α-amylase inhibitor(α-AI), which inhibits the animal saliva and pancreatic α-amylase, has been identified and isolated from various species of plants. Among these plants, seeds of Phaseolus vulgaris L. containing protein inhibitor seed α-amylase inhibitor-1 iso-form α-AI have been isolated and characterized. A α-AI common bean-1 has been reported to have relatively great potential as an anti-obesity and anti-diabetes remedy extensive.

Plant extracts are the potential inhibitors of α-amylase: a review

Diabetes was multi factorial in origin and therapeutic approach to treat diabetes was to delay glucose absorption through the inhibition of enzymes α-amylase. Brown extracts of rice was also evaluated for its α-amylase inhibitory potential. Inhibitors α-amylase digestion and absorption of carbohydrates glucose lag, and therefore could be beneficial against the onset of type 2 diabetes.24

The inhibitory activity of α-amylase shown in Figure 1. As the results, in free phenolic compounds, extracts of red rice have the highest inhibition activity (78.56%), while extracts from black rice have lower activity inhibition (53.63%) and inhibition activity of extracts of black rice was (68.16%). Similarly, in consolidated form, inhibition activity was greater in extracts of red rice (48.67%) and lowest in extracts of white rice (30.60%). Free forms of phenolic compounds always have the highest inhibiting activity of phenolic compounds bound form three types of rice.

Figure 1 Alpha-amylase % inhibition activities in various types of rice.

Inhibition activities of α-amylase free and bound phenolics. In some previous studies, the presence of α-amylase inhibitors have also been reported in grains,25 wheat,26 Linumusita tissimum L., sorghum,23 maize (Blanco-Labra and,21 peanuts.19 Linumusita tissimum L., and calluses.26 In the present study, we detected a high percentage inhibition in extracts of red rice (78.56%). These results indicate that phenol compounds in rice mainly existed in the free form rather than in bound form. There is a positive relationship between total phenolic content, antioxidant capacity and inhibition activity of α-amylase. It also confirms that the red brown rice not only consumed as functional foods, but also use as pharmaceutical drugs. As the mechanism and metabolism of brown rice extract involved in this inhibitory activity corresponding to type 2 diabetes α-amylase effect is unclear and work.

On bioavailability of phenolic compounds has been limited, it is vital to do more research on the metabolic pathway and functional mechanism of extract of brown rice on type 2 diabetes.27

Alpha amylose enzyme plays an important role in start breakdown complex carbohydrate into simple molecules. Intonation of α-amylase activity using affects carbohydrates as an energy source and this intonation stronger. Most significantly is decomposition of complex carbohydrates. Most studies have focused on phenolic compounds amylase antibodies. The proposed inhibitory capacity of flavonoids action mechanism correlates inhibition potency of these compounds with the number of hydroxyl groups in the B ring of the flavonoid skeleton with the formation of hydrogen bounds between the hydroxyl groups of the ligands polyphenol and the catalytic residues of the binding site of the enzyme. The high inhibitory capacity observed in flavonols and in their groups. It is20 suggested that the interaction between tannins, quinic acid as galloylated, α-amylase and human also correlates with free OH groups in the tannin, which are capable of participating in hydrogen bonding. However, in this review may notice that the tannins are not always an effective inhibitor of α-amylase. This compound showed 100% inhibition in 24 hours and 50% inhibition at same next time. The similar process was conducted to estimate this activity in both studies.29 However, the extract concentration and incubation time for tested enzyme were different for both.30 The study showed distinction in the concentration of the test compound and incubation time of the enzyme,16 the changes showed in the result clearly. Inhibitions of 85% and 50% rosmarinic acid and 23% and 55% for daidzein in tests using starch and nitropheny1-maltopenta side p-d-D-(PNPG) as substrate respectively.31 Comparing study of α-amylase inhibitory activity observe significant difference in the percentage inhibition for the same compound. This is due to a number of valuable test methods available for amylose activity.22

Conclusions and future developments

Alpha-amylase, salivary or pancreatic enzyme plays an important role in early break down complex carbohydrate into simple molecules. Modulation of α-amylase activity using affects carbohydrates as an energy source and this modulation is stronger. Most significantly is decomposition of complex carbohydrates. Therefore, some changes in the trials reported by investigators could express different results for the inhibitory activity of α-amylase. As the intake of phenolic compounds is associated with many beneficial effects, it is also necessary to consider the dosage for humans, because it is possible to reduce the activity of α-amylase by eating food or rich medicinal herbs in polyphenols with strong activity α-amylase, if one takes into consideration that this source of polyphenols have different types of these compounds in varying concentration. Therefore, the available evidence is most needed about the safety of using α-amylase inhibitors natural. From the above study it is concluded that, there is a need for new agents, therapeutic strategies or design of functional foods that could act in the physiological regulation of the absorption of sugar, sugar levels in the blood and prevention of oral diseases. For the future a standardized protocol for potential inhibitors perhaps should be developed in order to minimize the differences between the results obtained. Considering the above discussed literature and potent antidiabetic potentialities, ethno-medicinal plants may play a very important role in the modern system of medicine and these efforts may provide treatment to everyone and focus on the role of traditional novel medicine plants that have anti-diabetic abilities.
