Turner Syndrome And Atypical Malformations: A Case Report

Abstract
The Turner syndrome is a chromosomal aberration that is expressed by growth retardation and an impuberism. It can be associated with visceral, metabolic and endocrine diseases thus increasing the risk of morbidity and mortality. The isolated left ventricular non-compaction cardiomyopathy is a rare form of congenital cardiomyopathy. We report the case of a 38-year old female addressed from the Department of Cardiology for the exploration of a primary anamorhhea and a short stature. The clinical examination revealed a size: 145 cm (-3 SD/M. SEMPE) with a total impuberism. The hormonal tests showed a hypergonadotropic hypogonadism. Our patient was followed for cardiac heart failure. The echocardiographic exploration found a left systolic ventricular dysfunction with a septum akinia and an anterior wall hypokinesia. The left ventricular ejection fraction was 40%. It was therefore a dilated left ventricular non-compaction cardiomyopathy. The Turner syndrome and associated malformations should be diagnosed as early as possible to hope to improve the prognosis of the disease.

Introduction
The Turner syndrome is a chromosomal aberration that is expressed by growth retardation and an impuberism. It can be associated with visceral, metabolic and endocrine diseases thus increasing the risk of morbidity and mortality. The non-compaction isolated left ventricular (LVNC) is a rare form of congenital cardiomyopathy [1].

Case Presentation
We report the case of a 38-year old female addressed from the Department of Cardiology for the exploration of a primary amenorrhea and a short stature. In his personal history, we noted repeated episodes of bilateral otitis and psoriasis.

The clinical examination revealed a size 145 cm (-3 SD/M. SEMPE) with a total impuberism. The hormonal tests showed a hypergonadotropic hypogonadism. The abdominal CT scan revealed a left hemi-abdominal mass with a large vascular pedicle (supernumerary spleen?) Figure 1. Our patient was followed for cardiac heart failure. The echocardiographic exploration found a left systolic ventricular dysfunction with a septum akinia and an anterior wall hypokinesia. The left ventricular ejection fraction was 40%. It was therefore a dilated left ventricular non-compaction cardiomyopathy (Figure 2).

Discussion
The onset of the LVNC occurs during the fetal life [2]. It is the result of an in utero cessation of the myocardial maturation process explaining the spongy myocardium. Patients with LVNC are exposed to three types of complications such as the heart failure, the arrhythmias and the thromboembolic events. The LVNC is associated with mitochondrial disorders, Barth syndrome, and myotonic dystrophy [3]. The identified genes are FbSp1a/Notch pathway, G4.5 gene/TAZ protein, and others [4]. In the present state of our knowledge, the Turner syndrome and LVNC association has never been described in the literature, is it

fortuitous? The Turner syndrome and associated malformations should be diagnosed as early as possible to hope to improve the prognosis of the disease.
