A Review of Randomized Clinical Trials on the Effect of Aromatherapy with Lavender on Labor Pain Relief

Abstract

Background: Labor pain is a painful process and labor pain management is one of the essential aspects of obstetrical services and the main goal of intrapartum care. Aromatherapy is one of the traditional medicine methods for labor pain relief. This systematic review and meta-analysis aimed to critically evaluate and summarize all the available evidence from randomized clinical trials (RCTs) on the effect of aromatherapy with lavender on labor pain relief.

Methods: Scientific search was performed in MEDLINE/PubMed, Cochrane library, Cochrane Central Register of Controlled Trials (CENTRAL) and Scopus from their inception until September 2015 using the strategy (Lavender* OR Lavandula* OR silexan) AND (labor OR labour OR birth OR childbirth). In addition, we searched Google Scholar with the aim of exploring the citations of final studies included in the systematic review. Data extraction was done by two authors independently. Cochrane tool was used to evaluate the quality of citations. Comprehensive Meta-Analysis Version 2 was used for statistical analysis.

Results: Based on the search strategy, 192 primary papers were found. Finally, 3 RCTs were included in the systematic review. Overall, the quality of the studies included in the review was moderate and mixed. The results showed that lavender aromatherapy via inhalation decreased the labor pain by the order of -0.476[-1.438--0.375], p=0.001. Also, massage aromatherapy by lavender oil decreased the labor pain significantly (-0.907[-1.438--0.375], p=0.001). Conclusion: Although the results of this review showed the labor pain relief with lavender aromatherapy, more rigorous RCTs with higher quality is required to achieve a precise result.

Keywords: Aromatherapy; Lavender; Childbirth; Pain Management

Introduction

Childbirth is one of the most painful phenomena that women will tolerate in their lifetime. Labor pain is recognized as one of the most severe human pain [1,2]. Severe pain associated to vaginal delivery can cause abnormal uterine action during labor which might lead to increased medical interventions such as caesarian section (C/S) [3]. According to world health report, the rate of C/S in Iran is too high [4] and up to 60% of Iranian pregnancies. Aromatherapy is one of the traditional medicine methods for labor pain management options are non-invasive and safe for mother and fetus, their efficacy remains unclear due to a lack of high quality evidence [9,10]. In contrast, although most non-pharmaceutical pain management options are non-invasive and safe for mother and fetus, their efficacy remains unclear due to a lack of high quality evidence [9,10]. These methods are including heat and cold therapy, touch therapy, massage, reflexology, relaxation, dancing, chewing sugar free gum, trans or subcutaneous nerve stimulation, water therapy, using a birth ball, music therapy, acupressure and aromatherapy [11-13].

One of the non-pharmaceutical a method of labor pain relief is using of aromatherapy. Specifically, aromatherapy involves the use of essential oils to restore balance and improve well-being [14,15]. Several studies showed the effectiveness of aromatherapy for pain and anxiety relief of hospitalized patients [16], for relief of postoperative nausea and vomiting [17], on hemodynamic indices among patients with acute coronary syndrome [18] and side effects [9]. Also in the pharmaceutical methods, the pain feeling would be reduced physiologically, but psychological and emotional conditions of the childbearing mothers are ignored.

Non-pharmaceutical methods of labor pain relief are frequently simple to use, applicable and cheap, and can be used as a supplementary treatment with other pharmaceutical agents [10]. In contrast, although most non-pharmaceutical pain management options are non-invasive and safe for mother and fetus, their efficacy remains unclear due to a lack of high quality evidence [9,10]. These methods are including heat and cold therapy, touch therapy, massage, reflexology, relaxation, dancing, chewing sugar free gum, trans or subcutaneous nerve stimulation, water therapy, using a birth ball, music therapy, acupressure and aromatherapy [11-13].
improvement of life quality in women with breast cancer [19].
Also aromatherapy has many applications in women’s health,
including reduction of labor pain, episiotomy wound healing
[20], treatment of post C/S nausea [21], improvement of primary
dysmenorrhea [22], treatment of depression in postmenopausal
women [23]. Tillett’s study (2010) showed that the use of essential
oils has not been shown to cause complications and it has an
overall acceptability among women [24].

In general, various aromatherapy essences, including lavender,
eucalyptus, salvia, jasmine, and rose, are used in labor [25,26].
These essential oils are used in different ways including topical
application, inhalation, baths, and compresses [27].

Lavender (Lavandula angustifolia), which belongs to green
mint family and aromatic plants is one of the most used aromatic
plants in aromatherapy [28]. It consists of linalool, alcohol,
ketones, esters, and aldehydes. The ketones in lavender effectively
decrease pain and inflammation, and contribute to falling asleep.
Esters prevent muscle spasms, and reduce tension and depression
[29]. Jaradat [30] study showed that Lavender was a folk
medicinal plant with some Traditional uses such as treatment of
cough, eczema, rheumatism, migraine and was used as a diuretic,
carinative, and antispasmodic sedative [30].

Some studies suggest using Lavender aromatherapy for
pain and anxiety management during labor. However, the
effectiveness of non-pharmacologic approaches such as Lavender
aromatherapy on obstetric interventions and outcomes has
remained unclear; and there is still no consensus for the use of
Lavender aromatherapy for pain relief in hospital settings. The
difficulty to translate this approach into practice may be explained
by the lack of a systematic review assessing the impact of using
Lavender aromatherapy on labor pain relief.

Therefore, this systematic review and meta-analysis was
undertaken to critically summarize all the evidence from
randomized clinical trials (RCTs) of Lavender aromatherapy as
a supportive analgesic method during labor. The availability of
such information would be useful for all stakeholders such as
women, medicine and midwifery students, midwives, nurses,
gynecologists and health policymakers.

Methods

Data sources and search strategy

Two of authors conducted search in the MEDLINE/PubMed,
Cochrane library, Cochrane Central Register of Controlled Trials
(CENTRAL) and Scopus from their inception to September 2015.
In addition, we searched data base of Google Scholar with the
aim of exploring the citations of final studies included in the
systematic review.

The search strategy used was: (Lavender* OR Lavandula*
OR silexan) AND (labor OR labour OR Obstetric OR birth OR
childbirth). We imposed no language restrictions. The reference
lists of papers were checked for further relevant citations.
Personal contact was made with the authors of the studies, if
necessary, to request for additional data.

Inclusion criteria

We planned to include RCTs for inclusion in this review. We
considered studies for inclusion in this systematic review in
which Lavender aromatherapy was explicated in any form during
any stage of labor to relieve the labor pain. Gray literature was not
included.

Outcome measure

Our outcome measure was pain relief during labor. This is
usually measured with a 10 cm visual analogue scale (VAS) which
is a sensitive and efficient method for measuring pain. We used
difference in means of pre/post intervention VAS changes in the
treatment group as compared to the placebo, as the main effect
size measure.

Study selection

Two authors independently reviewed the titles and abstracts
of the records identified through database searching and excluded
irrelevant studies. Then they independently retrieved the full paper of seemingly relevant studies and examined them
to select the final set of included studies based on the inclusion
criteria. Any type of disagreement between authors was resolved
by discussion.

Data extraction

The reviewers designed a data extraction form. Data were
extracted by two reviewers using the agreed form, independently.
This included: first author’s name, year of publication, country,
participants, intervention and comparison, as well as outcome.
Disagreements were resolved by discussion and consensus.

Risk of bias assessment

All Studies included in the systematic review were assessed
by two reviewers independently for their risk of bias using the
Cochrane risk of bias tool [31]. This tool consists of some domains
including sequence generation; allocation concealment; blinding
of participants and personnel, blinding of outcomes assessors;
incomplete outcome data; selective outcome reporting; and other
source of bias. Each domain was rated as low, unclear, or high risk.
Disagreements were resolved by discussion and consensus.

Statistical analysis

We used random effects model in order to pool effect sizes
across the included studies. For heterogeneity evaluation,
Cochrane Q value (p<0.05 was considered statistically significant)
and I2 index were used. Meta-analysis results were expressed
graphically as forest plots. All statistical analyses were done by
CMA version 2.2.

Results

Results of the search

Figure 1 shows the PRISMA flow diagram for study inclusion.
The electronic search led to 192 publications. After excluding the
irrelevant records based on the title and abstract review, 6 studies
were reviewed by their full text, among which 3 were excluded.

Citation: Makvandi S, Mirtieimoori M, Najmabadi KM, Sadeghi R (2016) A Review of Randomized Clinical Trials on the Effect of Aromatherapy with Lavender on Labor Pain Relief. Nurse Care Open Acces J 1(3): 00014. DOI: 10.15406/ncoaj.2016.01.00014
due to duplication and 3 studies met our inclusion criteria. The RCTs were published between 2012 and 2014. Characteristics of included studies are presented in Table 1.

Participants and settings

Studies included in the systematic review ranged from 90 [32] to 160 [33] participants per study. Two studies recruited nulliparous women. Multiparous women were recruited in one study [34]. In two of trials studies the intervention was performed at the beginning of active phase of labor [32,33]. In another study it was not mentioned clearly [34]. All of studies were conducted in Iran.

Types of intervention

In two of studies, Lavender aromatherapy was applied via inhalation method: conducted cool vapor of essential oil of lavender [34] or Lavender oil mixed with water on the tissues attached to gown close to nostril [33]. Mohamadkhani [32] had used massage aromatherapy with Lavender oil mixed in Almond oil [32]. In two trials studies, the duration of time assigned to the aromatherapy intervention was not mentioned [33,34]. Mohamadkhani [32] had explained that aromatherapy was applied for 3×20 min during and between contractions [32].

Types of control groups

In trials related to inhalation Lavender aromatherapy, aromatherapy was compared with cool water vapor [34] or tissues impregnated with a few drops of water [33]. In massage aromatherapy control groups were massage with Almond oil or only massage [32].

Description of risk of bias

Figure 2 as a methodological quality graph shows a summary of the risk of bias assessments for all of the included studies. The methodological quality summary for each included study has been summarized in Figure 3. Overall, no one of the included trials was at a low risk of bias on all of domains. The method of sequence generation was not mentioned in one of included studies [33]. The methods used to conceal group allocation were also frequently not described in trials [32,33]. Only Vakilian’s studies reported adequate allocation concealment using numbered sealed opaque envelopes [34]. In most of trials the intervention could not be administered blind to participants or clinical careers. So, all of including studies had a high or unclear risk of performance bias. Vakilian’s study had an unclear risk of detection bias; as the blinding of outcomes assessors to group allocation was not described [34]. One study had a high risk of attrition bias which all of C/S births were excluded from analysis of labor pain; also the proportions of missing data were unbalanced across the groups [34]. The risk of reporting bias was at a low risk of bias in two of trials [33,34].

Outcome measures

Figure 4 shows the forest plot of Lavender aromatherapy effect on the labor pain. The results showed that Lavender
aromatherapy via inhalation decreased the labor pain by the order of \(-0.476\[-0.718--0.235\], p=0.000\). Cochrane Q value was 0.14, df=1 p=0.70 and I2=0%. Also, massage aromatherapy by lavender oil decreased the labor pain significantly \(-0.907\[-1.438--0.375\], p=0.001\).

### Discussion

An overview of the results of clinical trials presented that Lavender aromatherapy in laboring women can reduce labor pain. The main mechanism of aromatherapy remains unknown. Some studies showed that aromatherapy with essential oils does not cause any change in blood pressure or heart rate and also improves physiological indices such as mental state, mood and anxiety level [35]. There is a close relationship between anxiety and labor pain, followed by fear of childbirth may cause maternal anxiety during labor and stimulate the autonomous nervous system and expand hormonal secretion such as adrenaline and noradrenaline and cortisol. One of the mechanisms of action of Lavender aromatherapy is that Lavender oil in the role of an essential oil is absorbed through breathing and can reduce cortisol secretion or increase serotonin. Secretion As the findings of Mirzaei's study showed that Lavender aromatherapy reduced the level of maternal anxiety, cortisol secretion and increased serotonin secretion of the digestive tract during labor [36,37].

**Citation:** Makvandi S, Mirtaimoori M, Najmabadi KM, Sadeghi R (2016) A Review of Randomized Clinical Trials on the Effect of Aromatherapy with Lavender on Labor Pain Relief. Nurse Care Open Acces J 1(3): 00014. DOI: 10.15406/ncoaj.2016.01.00014
The primary components of lavender oil are linalool (51%) and linalyl acetate (35%). Linalool inhibits the release of acetylcholine and makes changes in ion channel function at the neuromuscular junction. In addition, linalyl acetate has narcotic effects and linalool also acts as a sedative. This function shows the justification for the use of Lavender oil in traditional herbal medicine. Since the massage facilitates the absorption of essential oils from the skin, so linalool and linalyl acetate will be absorbed within 5 minutes of skin massage and plasma concentration will be reached its maximum after about 20 minutes [38-40]. In addition, the decrease in labor pain that occurs with aromatherapy might be attributed to distraction from sense of pain. Distraction includes providing childbearing women with specific activities so that conscious thoughts and anxieties are reduced [41]. It seems that the smell of lavender or massage action, are along with a lack of focus on labor pain.

The authors of this meta-analysis, tried to minimize potential biases that threat the validity of the study. For example, our search strategy was comprehensive. Two authors independently performed the search, extracted data, and assessed each study quality. Also, no time and language limits were considered in searching. There were several issues in the context of clinical trials included in this review which readers should bear them in mind when reading and interpreting the results. In general, the quality of clinical trials was moderate. Most of the studies presented few details about the exact method. In some of studies binding of participants was impossible. Also a high level of attrition in one of the studies [34] means that the primary balance was created by random assignment of subjects to intervention and control groups may be damaged. Another potential limitation was the small sample size of clinical trials.

Conclusion

Although the results of clinical trials showed a reduction in labor pain with Lavender aromatherapy via massage and inhalation, but the authors of the study believe that more accurate clinical trials with particular attention to blinding, attrition and selective reporting of outcomes are necessary to create evidence-based guidelines on the use of Lavender aromatherapy for parturient women in reducing labor pain.
