

Bariatric surgery for obesity: a systematic review and meta-analysis

Abstract

Obesity is the fifth leading cause of global deaths. The efficacy and safety of obesity treatment is still controversial. The objective of the study is to evaluate the efficacy of bariatric surgery, through a systematic review of the current evidence and meta-analysis of important outcomes. Nineteen (19) randomized controlled trials (RCTs) with 1346 participants were included. Bariatric surgery resulted in greater weight loss when compared to non-surgical treatment. Weight loss was also associated with resolution and/or improvement of obesity related co-morbidities such as diabetes, hypertension, hyperlipidemia and sleep apnea. Weight loss and safety varied across the surgical procedures. Biliopancreatic diversion/duodenal switch had the greatest weight loss, followed by sleeve gastrectomy and Roux-en-Y gastric bypass, purely restrictive procedures such as vertical banded gastroplasty and adjustable gastric banding resulted in the least weight loss.

Keywords: obesity/surgery, gastric bypass, sleeve gastrectomy, bariatric, gastric banding, anastomosis, roux-en-y, biliopancreatic diversion (including duodenal switch)

Introduction

Overweight and obesity represent a major health challenge and are considered to be the fifth leading risk for global death and a major burden on health care systems.¹ Body Mass Index (BMI) is the most commonly used measure for classifying overweight and obesity in adults. The World Health Organization (WHO) defines overweight as a BMI of 25 or more, obesity as a BMI of 30 or more and morbid obesity as a BMI of 40 or more.² In the US, the prevalence of overweight and obesity in adults is estimated at 66.3% and 32.2% respectively³ and the prevalence of morbid obesity is approximately 5.1%.⁴

Non-surgical options for treatment of obesity include behavioral modification (dietary modification, caloric restriction, enhanced physical activity and psycho-interventions), pharmacotherapy, with or without organization supervision. These treatment modalities generally achieve only minimal and often transient effects with poor long term results.^{5,6} The raise in the prevalence of obesity led to increase interest in the surgical approach to treat obesity, and in 1991, the National Institutes of Health established guidelines for surgical therapy of morbid obesity (BMI \geq 40 or BMI \geq 35 in the presence of significant co-morbidities) now known as bariatric surgery.⁷ In the recent years, the demand for bariatric surgery has significantly increased; in 2008, approximately 350,000 operations were performed worldwide; 220,000 of these in the US and Canada.

The objectives of this study are to evaluate the effectiveness and safety of surgical and non-surgical treatments for obesity and whether they modify clinically important outcomes, including weight loss, co-morbidity modifications to diabetes, hyperlipidemia, hypertension,

and obstructive sleep apnea in adolescents and the adult obese population.

Material and methods

Data source and study selection

Randomized controlled trials (RCTs) comparing bariatric surgical procedures versus usual care (no treatment or medical management) or head-to-head comparisons of different surgical procedures were searched on the Ovid interface: MEDLINE Daily Update, MEDLINE In-Process & Other Non-Indexed Citations (1950 to December 8 2012), EMBASE (1947 to December 8 2012) and the Cochrane Library (until the fourth quarter 2012). The search strategy used both controlled vocabulary - the National Library of Medicine's MeSH (Medical Subject Headings). The search was not restricted to language and studies for which only abstracts were available were not considered.

Two reviewers (Hakeem Alobaid and Joan Peterson) independently performed an initial screening of articles by examining titles, abstracts and keywords for relevance to the research question. In case of disagreement or in the presence of insufficient information, the full text of the study was reviewed for eligibility. The decision to include articles in this study was reached by consensus. In cases where consensus was not achieved, a third reviewer (George Wells) was added to the selection process.

Inclusion and exclusion criteria

A study was eligible for inclusion if it satisfied each of the criteria listed below:

1. Study design: Randomized controlled trial (RCT).
2. Population: Adults who fulfill the definition of obesity i.e. BMI more than 30, and adolescents who fulfill the definition of obesity for age, sex, and height.

- Interventions: Five types of bariatric surgery procedures; Roux-en-Y gastric bypass, vertical banded gastroplasty, adjustable gastric banding, biliopancreatic diversion (BPD) and sleeve gastrectomy.

Exclusion criteria were: studies conducted on pediatric patients and non-controlled trials were not considered for analysis. Furthermore, studies that compared different techniques of the same procedure were excluded as well as those who compared techniques that are no longer used (e.g. jejunioileal bypass).

Outcomes

The measured outcomes of this study included:

- Weight modifications: Percent of excess weight loss (EWL), BMI loss, and weight changes (Kg).
- Co-morbidity modifications: Resolution of obesity related co-morbidities (diabetes, hyperlipidemia, hypertension, and obstructive sleep apnea).

Data extraction

One reviewer (Hakeem Alobaid) extracted data from the selected studies, and a second reviewer (Joan Peterson) checked the extracted data for accuracy. Any differences were resolved by consensus. The following variables were collected: the name of the primary author, journal and status of publication, country (countries) where the study was carried out, number of patients randomized in each group, mean age, study duration and inclusion and exclusion criteria. Clinical variables extracted were: patient weight, BMI, estimated weight loss (EWL), co-morbidity modifications to diabetes, hyperlipidemia, hypertension, and obstructive sleep apnea.

Assessment of study quality

Methodological quality of the studies was assessed using the SIGN50. A Guideline Developer's Handbook published by the Scottish Intercollegiate Guidelines Network⁸ which considered the appropriateness and clarity of the question, randomization, concealment, blinding, baseline comparability, group difference, outcome measurement, drop out, intention-to-treat analysis, site result, overall bias, and funding.

The risk of bias in the included studies was assessed using The Cochrane Handbook for Systematic Reviews of Interventions⁹ which considered the following factors: sequence generation, concealment, blinding, incomplete data, selective reporting and other bias.

The same two reviewers independently assessed the quality of the included studies. Prior to assessment, a calibration exercise was undertaken to ensure consistency in assessing or scoring between the two reviewers. Differences were discussed and resolved by consensus. In cases where consensus was not achieved, the third reviewer assisted with the study quality assessment process.

Statistical analysis

RevMan 5.1¹⁰ was used to analyze the result of the studies. Data were summarized in the meta-analysis if they were both clinically and statistically homogeneous. A random effects model was employed. Continuous data was expressed as mean difference (MD). In the few studies where measures of variance were missing from a relevant article, it was imputed from other information provided by the article (e.g. standard error (SE), p-value, 95% confidence interval (CI)).

Before the quantitative pooling of the results, the homogeneity of the clinical and methodological characteristics of included studies was evaluated. The characteristics reviewed included study design, inclusion and exclusion criteria, baseline demographics (age, gender), interventions, and clinical outcomes. Heterogeneity was measured with the I^2 statistic, with $I^2 \geq 50\%$ identifying substantial heterogeneity.¹¹

Results

Ascertainment of the studies

After initial screening, a total of 2006 potential studies were identified. Hand searching of the bibliographies of key papers and contacting appropriate experts resulted in additional 125 records. A total of 2131 records were screened. We excluded 2026 based on title or abstract. We retrieved 105 full text articles. Eighty five articles were excluded after reviewing the full text. A total of 19 studies met the inclusion criteria for the qualitative synthesis and 18 articles met the inclusion criteria for the quantitative synthesis (Figure 1).

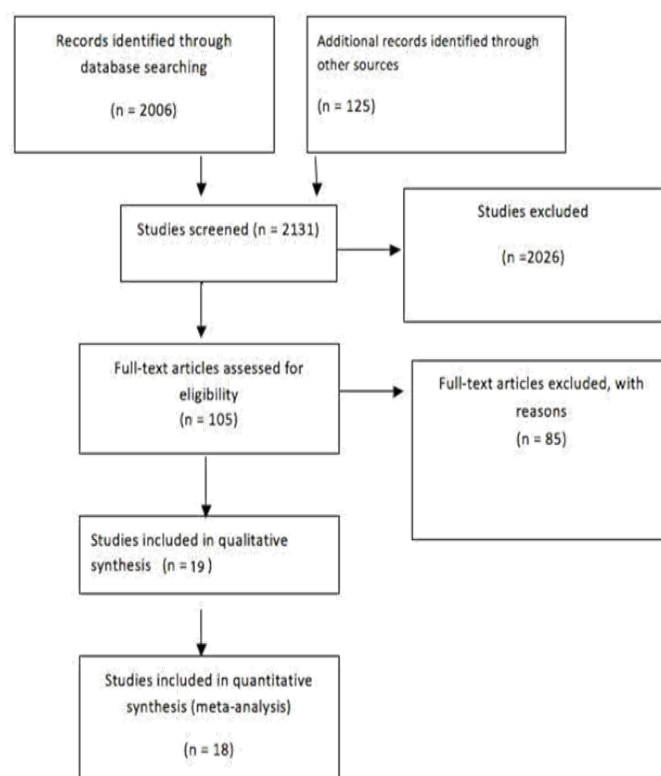

Figure 1 Search result flow diagram.

Study Characteristics

Table 1 summarizes the characteristics of all included studies. All the studies were single centre randomized control trials except for one trial¹² which was conducted in two centers. Sample size ranged from 20¹³ to 197.¹⁴ The included studies compared variety of interventions (Figure 2). Five RCTs^{13,15-18} compared surgical interventions to non-surgical interventions.

Four of the five were done in an adult population^{13,16-18} and one RCT was done in an adolescent population.¹⁵ Fourteen RCTs compared different surgical procedures (Figure 2).

QA= Qualitative Assessment

All the studies reported on weight changes but used different measures, mostly BMI, weight and percentage of excess weight loss. Resolutions of co-morbidities were reported in eight trials^{15-17, 19-23} (Table 1).

Risk of bias

We assessed the risk of bias for all the included studies; adequate concealment methods were described in three studies.^{13,16,29} Most other trials did not report the allocation process in sufficient details

to determine concealment. Four trials reported that outcome assessors were not blinded,^{15-17,27} one trial was blinded²¹ and the remaining trials did not report blinding. Methods of handling missing data and drop-outs were also assessed; three trials provided the number of dropouts along with the reasons for the dropout.^{15,28,30} Six trials did not report the reasons for the dropout.^{14,16,17,24,27,29} Two trials did not report on missing data.^{23,25} Adverse events were either not reported or not reported adequately in five trials.^{13,18,21,22,27} All outcomes were pre-specified in the methods section and reported as results in four trials.^{14,16,28,29}

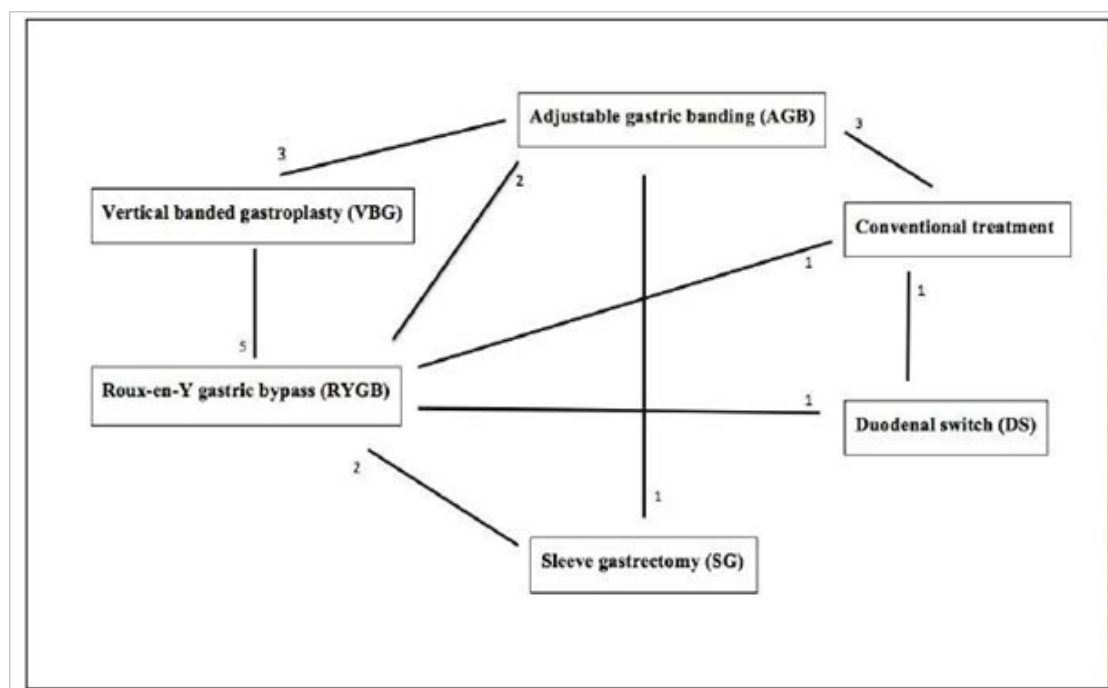

Figure 2 Network of comparisons of surgical and non-surgical interventions.

Publication bias and other sensitivity analyses: There were too few studies in any particular comparison to assess publication bias or sensitivity analysis.

Outcomes

Weight changes: There were three measured primary end points for weight changes in the meta-analysis: percent of excess weight loss (%EWL), body mass index loss (BMI), and weight loss (WT) in Kilograms, measured at one, two and three years.

EWL at one year: Based on the evidence at 1year, BPD/DS produced a significantly superior % EWL compared to LRYGB [MD

20.4% (95% CI: 14.3 to 26.5)] and conventional therapy [MD 49.8% (95% CI: 44.7 to 54.9)]. However, when compared to LAGB and LVBG at 1year, LRYGB resulted in a significantly superior weight loss [MD 20.5% (95% CI: 5.61 to 35.35) and MD 9.5% (95% CI: 2.76 to 16.32)]. LVBG had a better weight loss at one year compared to LAGB [MD -23.1(95%CI: -30.9 to -15.20)]. In terms of open techniques, RGYB had a better weight loss compared to open VBG and open VBG was also superior when compared to LAGB. Finally sleeve gastrectomy was superior to both LAGB and LRYGB [MD -16.3 (95% CI: - 26.09 to -6.5)] and [MD -9.2 (95% CI: -18.07-0.33)] respectively (Figure 3).^{14,16,18,22,23,25-27}

Figure 3 Excess Weight loss at 1year interval.

At 2years when compared to conventional therapy, LRYGB produced a significantly greater percent excess weight loss [MD 74.6% (95% CI: 61.7 to 87.5)].¹³

At 3year time interval, one study compared EWL between LAGB and LRYGB with results favoring LRYGB [MD 22.18% (95% CI: 12.66 to 31.70)].¹⁴ Furthermore, open RYGB had significantly better results when compared to open VBG [MD 27.5 % (95% CI: 20.09 to 34.9)]²⁶ (Figure 4).

BMI: LRYGB produced a significantly greater body mass index unit loss compared to LAGB [MD 3.7kg/m² (95% CI: 1.2 to 6.2)] and LVBG [MD 2.98kg/m² (95% CI: 0.49 to 5.47)]. When compared to LAGB, LVBG had better BMI loss [MD -4.9 (95% CI: -6.1 to -3.6)]. Sleeve gastrectomy had better BMI loss at one year when compared to both LAGB and LRYGB (Figure 5).^{15,18,19,22,23,29} At 2year interval LAGB had favorable BMI improvement when compared to conventional therapy [MD 7.55 (95% CI: 4.93 to 10.17)].¹⁷ however, LVBG had favorable outcome when compared to LAGB during the

same time period [MD -4.6 (95% CI: -5.89 to -3.31)].²⁹ At 3year time point, LRYGB had favorable results compared to LAGB [MD 6.97 (95% CI: 5.62 to 8.32)].¹⁹

-Weight loss: BPD/DS produced significantly more weight loss compared to LRYGB at 1year [MD 19kg (95% CI: 7.8 to 30.2)] and

more profound results compared to conventional therapy at 1year [MD 35kg (95% CI: 25.8 to 44.8)]. Open VBG produced significantly better weight loss when compared to ABG, yet, significantly worse weight loss when compared to open RYGB (Figure 6).^{16,18,24,26} At 3years, LRYGB produced favorable weight loss results compared to LAGB [MD 16.3 (95% CI: 7.83 to 24.77)] (Figure 7).¹⁹

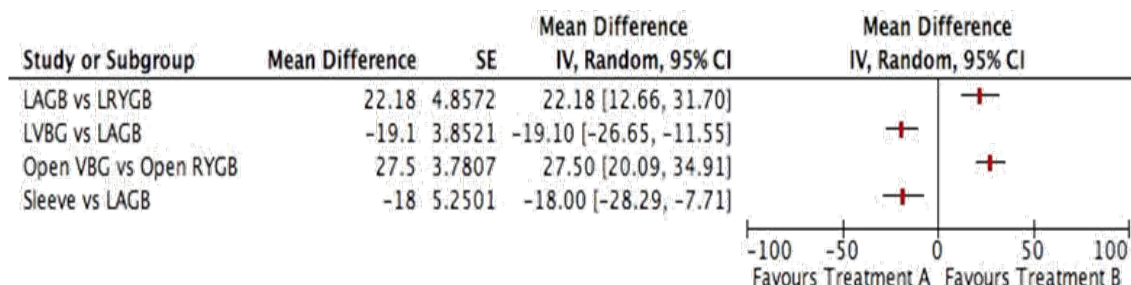

Figure 4 Excess Weight loss at 3year interval.

Figure 5 Body mass index loss at 1year interval.

Figure 6 Weight loss at 1year interval.

Figure 7 Weight loss at 3year interval.

Resolution of co-morbidities: Five RCTs^{13,15-18} compared surgical to nonsurgical interventions. Four of the five were conducted in adult^{13,16-18} populations and one in adolescents.¹⁵ Of the five RCTs: three compared adjustable gastric banding to conventional.¹⁵⁻¹⁷ One trial¹³ compared LRYGB to conventional therapy and one RCT¹⁸ compared biliopancreatic diversion and duodenal switch to diet. Of those studies, one trial,¹⁷ compared LAGB to conventional therapy in type 2 diabetic patients and found a higher remission rate in

the surgical group (73% vs 13% $P<0.001$). In addition, patients in this study discontinued antihypertensive medications (70% vs 0% $P<0.001$) and lipid lowering agents (67% vs 13% $P=0.02$). Similar findings were reported by two other trials^{15,16} compared LAGB to conventional therapy and found more patients with resolution of metabolic syndrome following bariatric surgery (93% vs 46% $P=0.006$) and (100% vs 60% $P<0.025$) respectively.

One trial¹⁹ compared LRYGB to LAGB and reported resolution of diabetes, sleep apnea, and hyperlipidemia in all patients who suffered from these co-morbidities prior to entrance into the study. Himpens²³ compared sleeve gastrectomy to LAGB and found resolution of gastroesophageal reflux disease (GERD) in more than 75% of participants following surgery. Karamanakos²¹ compared LSG to LRYGB and found significant reduction in glucose and triglyceride levels in both groups following surgery, as well as resolution of diabetes in all participants in the LRYGB group. Van Dielen²⁰ compared LAGB to open VBG and found that all co-morbidities had a tendency to decrease over time in both groups. Joint and pulmonary problems as well as diabetes showed the greatest improvement in co-morbidities after surgery. Lee²⁵ compared LRYGB to LVBG and found significant reduction in obesity-related clinical and laboratory abnormalities including blood pressure, blood glucose level, cholesterol level, triglyceride levels, uric acid levels, and liver function test.

Discussion

Obesity is a major medical and socioeconomic problem associated with different illnesses among them type 2 diabetes mellitus, high blood pressure, gallstones, certain types of cancer, gastroesophageal reflux disease, fatty liver, degenerative joint diseases, obstructive sleep apnea syndrome, and psychiatric diseases. Over the past two decades, the use of bariatric surgery to treat morbid obesity has increased dramatically. Surgery is markedly superior to conservative treatment with respect to weight reduction and alleviation of illnesses caused by obesity.

In this study, we incorporated 19 RCTs evaluating the effectiveness of surgical and non-surgical treatments for obesity and whether they modify clinically important outcomes, including weight loss, co-morbidity modifications to diabetes, hyperlipidemia, hypertension, and obstructive sleep apnea in adolescents and the adult obese population. The results of this study confirmed that bariatric surgery resulted in greater weight loss when compared to non-surgical treatment. Weight loss was also associated with resolution and/or improvement of obesity related co-morbidities such as diabetes, hypertension, hyperlipidemia, and sleep apnea. The effectiveness of bariatric procedures varied across the procedures, where malabsorptive procedures such as biliopancreatic diversion had the greatest weight loss results. Second to BPD was sleeve gastrectomy. Malabsorptive and restrictive procedures such as Roux-en-Y gastric bypass resulted in intermediate weight loss and restrictive procedures such as AGB and VBG caused the least amount of weight loss.

Our results are in an agreement with other reports from observational studies as well as systematic reviews and meta-analysis. In 2004, Sjostrom et al.,³¹ published a land mark cohort study in the New England Journal of Medicine with a total of 4047 participants, of these 2010 underwent bariatric and all followed for 10 years, found that weight has increased in the conventional treated group by 1.6%, where weight has decrease in the surgical group by 16.1%. Recovery from obesity related

Co-morbidities were more frequent in the surgical group than in the conventional group. A systematic review and meta-analysis that included observational studies to evaluate the impact of bariatric surgery on type 2 diabetes and found to have dramatic impact where 78.1% of the participants in the surgical group had complete resolution of type 2 diabetes and 86.6% had their diabetes improved or resolved, as well as similar result in term of weight loss, where biliopancreatic diversion/duodenal switch had the greatest weight loss followed by

gastric bypass, and least for banding procedures.³²

One of the limitations of this study is that most trials only provided short term follow-up (median follow-up was 2 years) and trials which provided a longer follow-up had high dropout rates. In addition, published trials did not provide enough detail to adequately assess the risk of bias, which consequently remains uncertain. Only 3 trials reported adequate concealment, which is considered a low risk of selection bias. Some variance measures necessary for meta-analysis were missing from a few trials, and this is considered a limitation to this review, as not all the data were available. Some procedures were assessed in only two trials such as sleeve gastrectomy and biliopancreatic diversion, and some trials did not report on safety at all.

On the other hand, this study also has several strengths. An extensive literature search was performed and provided the most up-to-date information on the outcomes of different bariatric procedures. Using two reviewers, the inclusion or exclusion of studies and data extraction were performed independently and therefore more accurately. In addition, we did not exclude potential studies due to language, publication status or year of publication. Another strength of this study is that we assessed not only the impact of bariatric procedures on weight reduction, but we also included its impact on the resolution of obesity related co-morbidities and compared different bariatric procedures to each other and to non operative conventional management.

In summary, this study has demonstrated that bariatric surgery is more effective than conventional therapy for the treatment of obesity. Weight loss associated with bariatric surgery led to improvement and remission of co-morbidities such as type 2 diabetes, hypertension, hypercholesterolemia, as well as significant reduction in the use of hypoglycemic agents, antihypertensive agents, and lipid lowering agents. Weight loss varied across the procedures, where biliopancreatic diversion with duodenal switch achieved the greatest weight loss, followed by sleeve gastrectomy, gastric bypass, followed by vertical banded gastroplasty, and finally adjustable gastric band achieved the least weight loss.
