Potato sprout inhibition and tuber quality after post-harvest treatment with rosemary (*Rosmarinus officinalis* L.) leaves and branches

**Abstract**

Storage of potatoes is one of the most important concerns in maintaining freshness and nutritional quality in the storage process. To achieve this, an experiment was carried out with five different storage conditions at various temperatures using fresh rosemary leaves and branches with three replicates. The results revealed that storage of potatoes at 25°C with rosemary leaves and branches resulted in the lowest sprout development and weight loss after 10 weeks. This was significantly different from either 4°C or 30°C. The findings indicated the potential of rosemary fresh leaves and branches to improve potato storage life considering its simplicity and efficacy in decreasing the storage cost, the weight loss and sprouting without causing any environmental toxicity.

In addition, the potential of rosemary could be used to other fruits and vegetables to investigate further the possible role of rosemary application to prevent fungal rot.

**Keywords:** potato, *Rosmarinus officinalis*, sprouting, storage life, temperature

**Introduction**

After rice and wheat, Potato (*Solanum tuberosum* L.) is the third most important food crop worldwide and provides high quality nutrition, especially food energy, vitamin C, potassium, protein and dietary fiber. Due to their short production cycle, potatoes provide food faster than cereals or legumes and produce more food calories per hectare, and use less water as compared to either wheat or rice. Storage conditions are an important issue in increasing the storage life and conservation of horticultural products such as potatoes. To assure high quality tubers after storage, it is necessary to begin with healthy, well-matured tubers of an appropriate cultivar for the intended purpose. However, several factors influence the final quality of potato tubers. These include duration of storage, dormancy status and physiological age, diseases and pests, temperature, relative humidity, application of postharvest chemicals and the composition of the atmosphere surrounding the stored tubers. Although fruits and vegetables are often treated with fungicides to delay postharvest disease, due to the adverse effects of chemicals on human life and environmental pollution, their application in the storage process is limited. Application of non-chemical methods, such as the use of gamma rays, UV light, heat therapy and natural products have been explored as an antioxidant and an antimicrobial agent.

**Materials and methods**

**Plant material**

Similar sized and shaped potatoes were provided from the Seed and Plant Improvement Institute, Karaj, Iran. The fresh leaves and branches of *Rosmarinus officinalis* were collected from the experimental field of the Medicinal Plants Research Center, Shahed University, Tehran, Iran.

**Experimental technique**

The experiment was conducted in the Department of Horticulture, Agriculture Science Faculty, Shahed University, Tehran, Iran, during August to November 2012. We carried out an experiment based on a randomized complete block design (RCBD) with five different storage conditions at various temperatures with and without using fresh rosemary leaves and branches, with three replicates. The storage conditions were: 4°C in a seed storage apparatus, 25 and 30°C without rosemary leaves and branches, and 25 and 30°C with rosemary leaves and branches in a controlled incubator. Five hundred grams of the similar sized and shaped potatoes were placed into each paper bag...
Potato sprout inhibition and tuber quality after post-harvest treatment with rosemary (Rosmarinus officinalis L.) leaves and branches.

The slope of the weight loss at 25°C using rosemary showed 2.51 g decrease per storage time (one week) followed by 30°C with using rosemary, 4, 25 and 30°C using rosemary leaves and branches. The slope of the average bud length at 30°C using rosemary showed 0.26 cm increase per storage time (one week) followed by 25°C using rosemary, 4, 25 and 30°C without using rosemary leaves and branches (Figure 2). This might be due to the effect of storage conditions during the experimental period. As shown in Figure 2, after 10 weeks, the highest and lowest decrease in WL was observed at 25°C without using rosemary leaves and branches, and 25°C using rosemary leaves and branches, respectively. Interestingly, the amount of decrease in 25°C using rosemary leaves and branches was the best condition with respect to the WL and the ABL (Figure 2).

Discussion

Storage of potatoes is one of the most important concerns in maintaining nutritional quality. Hence, any treatment, such as natural products that control and extend the storage life of potatoes, could be beneficial. In order to investigate the storage life of potatoes, a set of critical post-harvest related indices such as weight loss and sprouting of potatoes were evaluated under different storage conditions. Since refrigerated storage controls the respiration rate of harvested crop products, it delays the following causes of deterioration of crops including: aging due to ripening, softening, color changes, undesirable metabolic changes, respiratory heat production, moisture loss, wilting and spoilage due to invasion by bacteria, fungi, and yeasts. Application of some natural products such as flavor compounds, acetic acid, jasmonates, glucosinolates, propolis, fusapyrone and deoxyfusapyrone, chitosan and essential oils for the management of fungal rotting of fruits and vegetables has been developed. Although the exploitation of natural products to protect the postharvest decay of perishable products is in its infancy, these products have the potential to be safe fungicides and could replace the synthetic ones. Our results revealed the importance of rosemary in improving the storage time by decreasing weight loss.

In a study on the essential oils of ten plants, recommended that the essential oils could be a potential source of eco-friendly botanical fungicide, after long term and wide ranging trials to exhibit absolute fungi toxic activity up to 100% growth inhibition. Bina et al. reported that the application of rosemary fresh leaves and branches can improved the storage life of onions considering its simplicity and efficacy in decreasing the storage cost, the weight loss and sprouting without causing any environmental toxicity. Therefore, applying rosemary leaves and branches to reduce germination and potato weight, the fungal infection and decay is the most effective approach as compared to the recommended chemical sorirradiation storage in potato bulbs. Our results indicated that sprouting (the average bud length) of all treatments except the rosemary treatment increased at temperatures above 4°C. Variation due to storage conditions was significant in terms of sprouting, average bud length; number of active buds and tuber weight. In agreement with the reports of Struik & Van Ittersum et al., the findings of this study indicated that high temperature decreased the storage time and increased the weight loss and the average length of sprouts, while high temperature along with applying rosemary leaves and branches increased storage time, and under these conditions, the weight loss and sprouting of potatoes were the lowest.

Our results revealed that the potato bulbs had no germination during the first two weeks but by increasing storage time potatoes started to germinate and therefore, the average bud length increased, which matched up with findings of Hartmans et al. who reported that with increasing storage temperature, the average bud length and number of sprouting of potato tubers were increased. The use of

Figure 1 The effects of storage conditions on the weight loss (A) and the average bud length (B) of potato during experimental period (10 weeks). Applying the Rosemary leaves and branches at 25°C storage conditions showed lowest the WL and the ABL.

Different letters indicate significant difference between the values of pair of treatments. Vertical bars represent SEM. for three samples. T1; 4°C in the incubator, T2; 25°C and T3; 30°C without rosemary leave and branches, T4; 25°C and T5; 30°C with rosemary leave and branches in the controlled seed storage apparatus, T2; 25°C and T3: 30°C without rosemary leave and branches, T4; 25°C and T5; 30°C with rosemary leave and braches in the controlled incubator.
herbal ingredients and essential oils in proper sensory tests is needed before making any recommendations. Maintaining the benefits of the plants as fungi toxicants which are effective on postharvest phases should be confirmed properly during accurate laboratory tests and the tests based in vivo experiments, while considering safety measures and applying the most important features. In order to make better use of rosemary and other herbs in postharvest storage of horticultural crops, it is recommended to complete the investigation of other forms of application, such as the use of essential oils or spraying to foliar tissue, and measure their effect on quality parameters such as taste and flavor of fruits and vegetables. As a final conclusion considering weight loss and sprouting (the average bud length) traits related to postharvest fruits and vegetables, the application of fresh rosemary leaves and branches can be considered as an alternative strategy to control postharvest fungal rotting of fruits and vegetables to improve the storage life of potatoes considering its simplicity and efficacy in decreasing the storage cost, weight loss and sprouting without causing any environmental toxicity. Therefore, the suggested approach can be applied to other postharvest fruits and vegetables for improving the storage life.
