A review on plastic bioaccumulation, potential health effects and the potential to enhance biotransformation using herbal medicine and nutritional supplements

Abstract

Background: Recent studies have highlighted that plastic contamination in air, food and drinking water is ubiquitous and evidence of plastic contamination in humans is growing. Plastic is a vector for heavy metal contamination and has been recently shown to cross the blood–brain barrier (BBB) in humans. Global concern regarding the health implications is mounting, with the World Health Organisation (WHO) having conducted a risk assessment review of plastics. Whilst knowledge gaps exist, we remain to eat, drink and inhale plastic toxins without knowing what harm it is potentially causing or how to detoxify it.

Aim: The aims of this review are to improve knowledge on the topic and to provide new insights on plastic bioaccumulation in humans, what is known about the potential health effects and how herbal medicine and nutritional supplements may assist plastic biotransformation.

Methods: I reviewed scientific articles in relation to the extent and sources of microplastic contamination, human biomonitoring studies, articles discussing potential human health implications, articles discussing how plastic toxins are biotransformed and articles examining herbal medicines and nutritional supplementation that support these detoxification processes.

Results: The results indicated biomonitoring studies in humans for persisted organic pollutants including toxins are not widespread, that research into biotransformation is a relatively new field and that no research exists that demonstrates how herbal medicines or nutritional supplements may enhance biotransformation to reduce the burden of human plastic contamination.

Conclusion: The findings help highlight that biomonitoring studies in humans need to be widely adopted to help ascertain the true extent of plastic bioaccumulation. Herbal medicine and nutritional supplements may be a valuable tool to enhance biotransformation of plastic contaminants in humans and further research into this area is warranted. The results and applications of this research have the potential to reduce endogenous EDCs and POPs in humans and thus may potentially lead to improved global health outcomes.

Keywords: plastic bioaccumulation, plastic biotransformation, microplastic, nanoplastic, microplastics in drinking-water, microplastic exposure and impacts on human health, complementary and alternative medicine (CAM), herbal medicine, nutritional supplements, pharmacognosy

L-methionine; SFN, sulforaphane; SOD, superoxide dismutase; TeR, T-cell receptor; TCDD, tetrachlorodibenzo-p-dioxin; TEQ, toxic equivalent; T2D, type 2 diabetes; US, united states; UDP, uridine diphosphate; UDPGA, Uridine diphosphate glucuronic acid; UGT, UDP-glucuronosyltransferase; WHO, world health organisation

Background

Plastic is a crude oil product a non-renewable energy source\(^1\)

The largest global consumer of oil is the United States (US) military, consuming 100million barrels of oil per year.\(^2\) Regardless of the ever-increasing abundance of evidence of fossil-fuelled climate change and billions in subsidies for alternative technologies, global oil consumption will reach 100million barrels per day, double what it was 50 years ago, with no sign of abating.\(^3\) The US alone uses 330million barrels of oil per year in plastics production alone,\(^4\) three times the US military use.

The scale of microplastic contamination is staggering

An estimated 8 million tons of plastic enters our oceans each year. Microplastics are omnipresent in sea waters, from deep-sea ocean sediments to the polar caps.\(^5\)

Microplastics contain and absorb toxic chemicals

Microplastics are a vector for heavy metal contamination from the marine environment.\(^6,7\) Microplastics attract harmful pathogenic bacteria in sewage and contain and absorb toxic chemicals. More than 50 persistent organic pollutants (POPs), in particular polychlorinated biphenyls (PCBs) and polycyclic aromatic hydrocarbons (PAHs) are found in the five most common types of plastic.\(^8\) POPs are also called persistent toxic substances (PTS).\(^9\)

Plastic in tap water globally

Billions of the global population are drinking water contaminated by plastic particles with 83% of samples found to be polluted. The US contamination rate was the highest at 94%. The next highest rates were found in Lebanon and India. The lowest contamination rates at 72% were found in Germany, France and the UK. Each 500ml sample was found to contain on average 4.8 plastic fibres in the US and 1.9 plastic fibres in Europe.\(^10,11\)

In 2017 an Irish study sampling tap and well water found microplastic contamination present in a small amount with the study author Dr Anne Marie Mahon, marine microplastic scientist from Galway-Mayo Institute of Technology (GMIT) advising that until we know what the health impact is we should adopt the precautionary principle.\(^12\)

Plastic in bottled water globally

The Orb study (Orb Media is a U.S-based non-profit journalism organisation) tested 259 bottles from 19 locations in 9 countries. 11 different brands were found to contain on average 325 plastic pieces of microplastic in every litre of water. Nile red dye was sued to fluoresce the particles of plastic in the water. This technique was developed by Dr Andrew Mayes of University of East Anglia. Nestlé Pure Life was found to have the highest levels of microplastic contamination with as many as 10,000 pieces of microplastic per litre. Only 17 of the 259 plastic water bottles tested were free of plastic.\(^13\) The contamination is thought to be in part derived from the packaging and bottling processes.\(^14\) Polypropylene plastic, the same plastic used to make bottle caps was the most common plastic piece found. Polypropylene (recycling number 5) is a considered a safe non-leaching plastic. The study was not published in a journal, nor has been peer reviewed. A second unrelated Story of Stuff Study in the US looked at 19 bottled water brands and found plastic pieces to be widely distributed. Bottled water was found to have twice the amount of microplastic than tap water (Appendix).\(^15\)

Appendix

The brands orb media tested

- a. Aqua (Danone)
- b. Aquafina (PepsiCo)
- c. Bisleri (Bisleri International)
- d. Dasani (Coca-Cola)
- e. Epura (PepsiCo)
- f. Evian (Danone)
- g. Gerolsteiner (Gerolsteiner Brunnen)
- h. Minalba (Grupo Edson Queiroz), Nestlé Pure Life (Nestlé)
- i. San Pellegrino (Nestlé)
- j. Wahaha (Hangzhou Wahaha Group)
- k. The bottles analysed were bought in the US, China, Brazil, India, Indonesia, Mexico, Lebanon, Kenya and Thailand.

The brands story of stuff tested

- a. Boxed Water contained an average of 58.6 plastic fibres per litre.
- b. Nestlé’s Ozarka and Ice Mountain had concentrations at 15 and 11 pieces per litre, respectively.
- c. Fiji Water had 12 plastic fibres per litre.

Plastic water bottles

Plastic water bottles are made from polyethylene terephthalate (PETE recycling code 1). This symbol is normally also found in soft drinks. PETE does not contain BPA or phthalates but studies have found that the endocrine disrupting chemical (EDC) antimony, a toxic phthalate ‘plasticiser’ used to make plastics flexible, leaches from PET bottles placed in the heat for prolonged periods of time.\(^16\) Reusable plastic drinking water bottles are or more generally now, were made from polycarbonate (recycling code 7). Polycarbonate is manufactured from BPA.\(^17\) Investigations show in some cases, BPA-free PETE containers might leach oestrogen-like chemicals.\(^18\)

Sources of environmental microplastic

Washing acrylic, polyester and nylon: Plastic derived, acrylic, polyester and nylon persist in the environment. Synthetic clothingsets to landfill breaks down to plastic microfiber pollution that contaminates ground and surface water. The estimates are that one truck load of clothes goes to landfill every second and one truckload of plastic enters the sea every second. Scientists estimate that plastic will outweigh fish in the sea by 2050.\(^19\) Acrylics are by far the most polluting with...
the average load of household washing shedding 750,000 microplastic fibres per load. This is 5 times greater than is shed by polyester-cotton. Drying synthetics in clothes dryer vents microplastic into the air.20,21

**Burning plastics:** Buring plastics releases endocrine disrupting cancer causing dioxins and furans the most toxic chemicals known to humankind.22

**Human sludge:** A 2017 study for the Environmental Protection Agency (EPA) co-written by Dr Anne Marie Mahon from the Marine from the Freshwater Research Centre, Galway-Mayo Institute of Technology (GMIT) identified sludge spreading and the washing of plastic by the recycling industry as significant sources of environmental microplastic. Estimates are that at least a billion microplastic fibres are spread on Irish farmland annually.23

**Plastic in teabags:** A recent study estimated that steeping one plastic containing teabag in 95 °C water temperature releases 11.6 billion microplastic fibres and 3.1 billion nanoplastic fibres into each cup of tea. The composition of particles released was found to be nyleon and PETE matching the original teabags. Scientists conducted a toxicity assessment which showed that exposure to the plastic particles leaching from the teabags caused harmful behavioural and developmental health effects and that these were dose-dependent.15 Non-biodegradable plastic contain teabags have been added to the municipal compost for decades.

### Extent of plastic contamination in food and air

**Plastic in beer, salt and well water:** German scientists tested 24 beer brands, honey and sugar and discovered microplastic fibres were found in all those tested. The study concluded the average person is ingesting 5,800 particles of plastic annually, with largest proportion (88%) of this contamination being attributed to tap water consumption.10

**Annual atmospheric microplastic fibres fallout on Paris:** Microplastics and nanoplastic fibres in our sea evaporate to provide a source of both outdoor and indoor air pollution. A study examining microplastic atmospheric fallout estimated an annually fall-out of between 3 and 10 tons of microplastic on Paris.24

### Evidence of plastic contamination in humans

**Biomonitoring programmes:** Biomonitoring human studies are evolving and useful for investigating exposure to phthalates, BPA and other chemicals. The U.S Center for Disease Control and Prevention (CDC) conducts a yearly National Health and Nutrition Examination Survey (NHANES). One of the objectives of the NHANES is to assess the number of POPs detected in high concentrations in the population. NHANES results indicate it is common for people to have low and high concentrations of a number POPs. In relation to plastic POPs the NHANES study measures;

a. Serum dioxins, furans and PCB
b. Urinary phthalates and BPA24

One NHANES study found 91 POPs analysed in blood samples and concluded that one tenth of the US population may have ≥10 POPs each at concentrations in the top decile.29

**Plastic in human stools**

9 different plastics have been found in all human stools tested.27

### Latest cause for concern

#### Nanoplastic passes the BBB in fish

Science has shown that nanoparticles or nanoplastic passes the blood-brain barrier (BBB) in fish resulting in behavioural disorders and brain damage.28

Most of the information we understand about the detrimental health effects of come from studies conducted in fish. The WHO is only just now looking into the health effects of plastics in humans.

The WHO launched a health review on microplastics in drinking water to review the very scarce evidence which they described as scarce, to highlight evidence gaps, establish an agenda for research and allow for a more informed and thorough risk assessment.

#### Endocrine disrupting chemicals and human health

Endocrine Disrupting Chemicals (EDCs) include organochlorine pesticides, PCBs, BPA, phthalates, dioxins and furans.29 Nearly 800 EDCs have the capacity to interfere with hormone receptors, hormone synthesis and hormone conversion. The three strands of evidence that give rise to concerns over EDCs include a high incidence and increasing rates of endocrine-related disease in the population, numerous observations of endocrine-related sequelae in the fauna and laboratory tests linking EDCs with detrimental human health outcomes.30

#### EDC diseases and disorders

The following information on EDC diseases and disorders is a summary of those highlighted in the State of the Science of Endocrine Disrupting Chemicals Report initiated by the WHO.30

**Infertility in males and females:** BPA can interfere with the hypothalamic-pituitary-ovarian/testicular axis (HPA), to increase hypothalamic gonadotropin-releasing hormone (GnRH) secretion and promote pituitary proliferation.30,31

**Low sperm count:** Up to 40% of young males have a low sperm count.30

**Genital malformations:** Cryptorchidism and hypospadias in baby boys.30

**Sharp increase in children born with intersex variation IV:** Ambiguous genitalia, hermaphrodite, pseudohermaphroditism etc.

**Sharp increase in the incidence of gender dysphoria, transgender and gender neutral:** It must be noted that Lesbian, Gay, Bisexual, Transgender, Queer or Questioning and Intersex (LGBTQI) existed pre-industrial revolution.30

**Precocious puberty in young girls:** This is a risk factor for breast cancer.

**Adverse pregnancy outcomes:** Including premature birth and low birth weight.

#### Neurobehavioral disorders

b. Neurological impairments (NIs) including neuropathies.

c. Neurodevelopmental disorders (NDDs) including attention deficit hyperactivity disorder (ADHD) and autism.

**Citation:** Harkin C. A review on plastic bioaccumulation, potential health effects and the potential to enhance biotransformation using herbal medicine and nutritional supplements. *Int J Complement Alt Med.* 2020;13(1):18-26. DOI: 10.15406/ijcam.2020.13.00487
d. Neurodegenerative diseases (NDGs) including Parkinson’s and Alzheimer’s disease, and amyotrophic lateral sclerosis (ALS). 30

e. POPs, BPA and phthalates exposure is associated. 32

Hormone dependent tumours: Including breast, endometrial, ovarian, prostate, testicular and thyroid (30).

Metabolic disorders:

Polycystic Ovary Syndrome (PCOS). 31

Metabolic syndrome: 32 Evidence shows that EDCs may contribute to the evolution of the obesity pandemic and metabolic disorders including Type 2 Diabetes (T2D). 33 Lipophilic POPs are linked to T2D. 34

Atopic disorders: Phthalates and BPA exposure are linked to the pathogenesis of allergies, asthma and atopic dermatitis. 30,35

Lowered vaccine response

A Faro Island study, where diets may include PCB contaminated whale blubber, on the vaccine repose of two birth cohorts, suggested that PCB exposure may reduce the immune response to childhood immunisations. 36 Another study on the vaccine response of Dutch preschool children measured humoral immunity by antibody levels for mumps, measles, and rubella after primary vaccination and found that prenatal PCB exposure measured as a higher dioxin toxic equivalent (TEQ) was associated with an increased number of lymphocytes, T-cells, and cluster of differentiation (CD) CD8+ (cytotoxic), CD4+ (memory), T-cell receptor (TcR) and CD3(+) (activated) T cells and lower antibody levels to mumps and measles at preschool age. 37

Health implications of microplastics according to the WHO

It was recently widely reported that the WHO report referred to finding no evidence of a current danger from microplastic. 38 It must be noted that WHO report is about microplastic in drinking water only. Microplastic is as previously described universal. The WHO report in fact identified knowledge gaps and made recommendations in respect to monitoring and management of microplastic in the environment in order to better assess health risks posed to humans and to better inform appropriate management actions. 39

Microplastic mitigation

BPA and phthalates and dioxin-like PCBs are ingested plastic toxins. Dioxins and furans are inhaled plastic toxins produced when plastic is burned. Dioxins, furans and dioxin-like PCBs are abbreviated names for a family of chemicals with similar toxicity and shared chemical characteristics. Dioxins and furans are also known as Tetrachlorodibenzo-p-dioxin (TCDD). TCDD was the contaminant in Agent Orange, the notorious herbicide used during the Vietnam War. 40

Mitigate environmental exposure

Mitigation strategies include avoiding drinking water in plastic bottles and using an end stage water filtration unit to filter public drinking water supplies. Avoiding plastic incineration will also mitigate exposure. Phthalates are most typically found in industrial solvents and lubricants, additives in the textile industry, in pesticides, floorings, roofing, wall coverings, cables, clothing, packaging materials, personal-care products and toys. 41 BPA is used in the manufacture of epoxy and polycarbonate plastic resins. Products derived from BPA are commonly used in safety equipment, protective coatings inside tin cans and as composites and sealants in dentistry. BPA exposure primarily results from the ingestion of contaminated food. 42

Plastic biotransformation

Measuring the burden of human exposure: BPA-glucuronide has terminal half-life of <6h, is rapidly excreted in urine and can be used as a biomarker of exposure to BPA. Exposure to these phthalates can be assessed using custom synthesised reference standards of specific oxidised metabolites of Diisononyl phthalate (DINP) and Diisodecyl phthalate (DIDP). Phthalates are quickly metabolised and excreted in urine. 43

What happens after exposure?

After ingestion, nanoplastic reaches the systemic blood circulation, distribute to a variety of body compartments and penetrates cells. 44 Plastic too large to pass through the gut wall still present a risk to human health as it is a vector for hydrophobic POPs and EDCs of a smaller molecular size that are capable of penetrating cells. 45

Understanding biotransformation of plastic

Research into human biotransformation and elimination systems is relatively new and continues to evolve.

Phase I and II liver detoxification pathways

Liver detoxification is a misnomer as Phase I and II Liver Detoxification Pathways also occur in kidney, intestine, lung, skin, prostate, and brain. In medical terminology toxicity is referred to as bioaccumulation and detoxification is referred to as biotransformation. Very little attention is being paid to human exposure to environmental chemicals and POPs.

Many toxic chemicals are fat-soluble, making them difficult to excrete. The P450 enzyme system turns lipophilic toxins into hydrophilic chemicals that are then able to be readily excreted in urine, bile and sweat. In the event that fat lipophilic toxins are not made hydrophilic, lipophilic chemicals have a high affinity for fat tissues and cell membranes and can accumulate. These lipophilic toxins may be stored for years and released during times of exercise, stress or fasting. 46

Plastic biotransformation

Bisphenol A

Accumulation of BPA induces cytochrome P450 (CYP450) enzyme activities. 47 In humans BPA is mainly metabolised by CYP2C and inhibits CYP17 activity. 48 BPA is rapidly metabolised by glucuronidation conjugation. 49 BPA is also metabolite of sulphation and glutathione conjugation. 50 Transferases including sulfotransferases, glutathione-S-transferases (GSTs) are also involved in BPA conjugation. 51 A fraction of absorbed BPA may distribute to body storage site (s) such as adipose tissue, followed by a slow, low-level release of BPA into the bloodstream. 52

Phthalates

Phthalates undergo a series of phase I hydrolysis and phase II conjugation reactions and are subsequently excreted in faeces and urine. 53 Phthalates induce CYP450 specifically CYP4 enzymes. 54
Phthalates are a metabolite of gluconuridation,\textsuperscript{55,56} glycine and sulphation conjugation.\textsuperscript{56,57}

**Dioxins, furans and dioxin-like PCBs**

People vary in capacity to eliminate TCDD. The elimination rate is much faster at higher than lower levels.\textsuperscript{59} TCDD induces a number of CYP450 enzymes systems.\textsuperscript{59} Accumulation of POPs, dioxins\textsuperscript{59,60} and furans induce cytochrome P450 enzyme systems.\textsuperscript{61} Dioxins, furans and PCBs are metabolites of either gluconuridation or sulphate conjugation, mainly in the liver and excreted in the bile or urine.\textsuperscript{62} Dioxins undergo glutathione\textsuperscript{63} sulphation, “gluconuridation”\textsuperscript{56} and glycine conjugation phase II reactions.\textsuperscript{63}

**Phase I – modification**

Phase I reactions occur in the liver and are catalysed by CYP450 mixed-function oxidase enzyme (MFO) chemical reactions including oxidation, reduction, hydrolysis, cyclization, decyclization (cyclization and decyclization have no relevance in plastic biotransformation) and hydroxylation. MFO enzymes inhabit hepatocytes membranes.

**Modification pathways involve**

a. Oxidation is process of being oxidised (combining chemically with oxygen/rust).

b. Reduction involves gaining of electrons by one atom involved in reaction.

c. Hydrolysis involves a chemical breakdown of a compound due to a water reaction.

d. Hydroxylation involves introduction of a hydroxyl group (\(-\text{OH}\)).\textsuperscript{46}

**Induction of phase I (over activity)**

Certain metabolites of Phase I reactions are readily excreted. Many Phase I products are not rapidly eliminated and undergo subsequent Phase II reactions. If not adequately supported or when excessive POPs exist, Phase I is induced producing high levels of damaging free radicals. In cases whereby these reactive molecules are not readily metabolised by Phase II conjugation this can result in damage to proteins, RNA, and DNA. Phase I can turn a nontoxic molecule into a toxic (mutagenic/carcinogenic) molecule hence contribute to early ageing and cancer pathogenesis.\textsuperscript{56,57}

**Phase II – conjugation**

In the hepatocytes, toxic metabolites undergo biotransformation and are conjugated using glutathione (GSH), sulphate, glucuronic acid or glycine. These reactions are catalysed by a large group of broad-specificity transferases, the most important being glutathione S-transferases (GSTs). Phase II conjugation reactions transform a fat soluble toxin into water-soluble chemical that can be excreted in bile, urine and sweat.

**Major phase II detoxification conjugation pathways include;\textsuperscript{56}**

**Glutathione (GSH):** Co-factor: Glutathione and endogenous antioxidants; Glutathione S-transferase (GST), superoxide dismutase (SOD), glutathione peroxidise (GPx), glutathione reductase (GR) and catalase (CAT).\textsuperscript{58} The glutathione S-transferases (GST family) are activated through cysteine, glutamic acid and glycine to make glutathione. BPA,\textsuperscript{59} dioxins, furans and PCBs undergo glutathione conjugation.\textsuperscript{63}

**Sulphation:** Co-factor: 3’-phosphoadenosine-5’-phosphosulfate (endogenously synthesised) Sulphation renders a xenobiotic less active but sometimes activates xenobiotics. Sulphation is involved in detoxification and hormone regulation. BPA, phthalates,\textsuperscript{50,56,57} dioxins, furans\textsuperscript{46,54} and PCBs undergo sulphation conjugation.

**Glycine conjugation:** Co-factor: Glycine is catalysed by glycine N-acetyltransferase.

**Glycine conjugation** is an important metabolic pathway which allows the for maintenance of sufficient coenzyme A (CoA) levels. Phthalates,\textsuperscript{56,57} dioxins,\textsuperscript{64} furans and PCBs undergo glycine conjugation.

**Glucuronidation:** Co-factor: Uridine diphosphate (UDP) UDP-glucuronic acid Uridine diphosphate glucuronic acid (UDPGA). β glucuronidase breaks the chemical bonds formed during the detoxification processes, thus allowing the recirculation of toxins.\textsuperscript{59} BPA, phthalates,\textsuperscript{49,53,56,70} dioxins, furans and PCBs\textsuperscript{60} undergo glucuronidation conjugation.

**Pharmacognostical objectives**

a. Inhibit CYP450

b. Induce conjugation

**Andrographis/ Chuan Xin Lion/King of the bitter**

Contains the diterpenolactones andrographolide, 14-deoxy-11-dehydroandrographolide, 14-deoxy-11-oxoandrogapholide, 5-hydroxy-7,8,2',3'-tetramethoxyflavone, neandrogapholide, paniculide-A, paniculide-B and paniculide-C inhibit CYP450.\textsuperscript{71}

**Bupleurum/Chai hu bupleurum falcatum**

Contains saikosaponins which inhibit CYP450, specifically CYP1A2, CYP2C9 and CYP3A4. The flavonoids and steroids, rutin, isoquercetin, isorhamnetin, quercetin, β-sitosterol, α-spiniasterol, daucosterol and α-spinasterol glucoside inhibit CYP450 specifically CYP3A4.\textsuperscript{71,72}

**Burdock/nui bang zi arctium lappa**

Contains lignans lappal A, diacrinigenin and arctigenin which inhibit CYP450.\textsuperscript{71}

**Centella/hi Xue Cao Centella asiatica**

Contains triterpenes madecassic acid, brahmic acid and asiatic acid which inhibit CYP450.\textsuperscript{71}

**Eleutherooccus/ci wu jia eleutherooccus senticosus**

Contains glycoses eleuthera A, B, C, D, E, F, G and eleutheroside C which inhibit CYP450.

**Scut Baic/huang qin scutellaria baicalensis**

Contains iridoid glycosides baicalein, wogonin and oroxylin which inhibit CYP450.
Inhibit phase I and induce phase II

Milk thistle silybum marianum

Contains flavonolignans silymarin, silybin A, silybin B, isosilybin A, isosilybin B, silychristin, isosilychristin, silydianin, and one flavonoid taxifolin which significantly inhibit CYP450. Silymarin restores depleted GSH to assist in glutathione conjugation. Milk thistle is rich in phytochemicals that can modulate UDP-glucuronosyltransferase (UGT) Phase II enzymes.

Globe artichoke/Yang ji cynara scolymus

Contains the flavonoid luteolin which inhibits CYP450 specifically CYP 3A4 and CYP3A5.

Barberry/fu niu berberis vulgaris

Contains the benzylisoquinoline alkaloid berberine which inhibits CYP450.

Turmeric /jiang huang curcuma longa

Contains the diarylheptanoid curcumin which inhibits CYP450 whilst inducing Phase II. Curcumin assists glutathione conjugation by restoring toxin-induced depleted GSH reserves. Curcumin induces nuclear factor-erythroid-2-related factor 2 (Nrf2), a leucine zipper (bZIP) protein that regulates expression of antioxidant proteins thereby protecting against oxidative damage triggered by injury and inflammation. Nrf2 regulates Phase-II enzymes.

Supplements

N-acetylcysteine

N-acetylcysteine (NAC) is a precursor to L-cysteine that results in GSH elevation biosynthesis. NAC increases GSH conjugation and is a powerful antioxidant/free radical scavenger.

Caclium D-Glucarate

Caclium D-Glucarate (CDG) inhibits β-glucuronidase, therefore enhances glucuronidation conjugation. CDG is in cruciferous vegetables or vegetables from the Brassicaceae family.

Sulforaphane

Sulforaphane (SFN), an isothiocyanate found in cruciferous vegetables inhibits CYP450 and induces Phase II.

Hesperidin

Hesperidin, a flavanone found in citrus fruits (oranges, lemons, pomelo), inhibits CYP450 and induces Phase II.

Grapefruit

Grapefruit contains the compound naringenin which inhibits CYP450 and induces Phase II.

Conclusion

As the awareness of microplastic contamination grows, so too does global concern regarding the health implications. Whilst reproductive and developmental abnormalities linked to EDC exposures in fauna are documented, the human health effects associated with full exposure of the whole gamut of endocrine-disrupting chemicals in the environment is yet to be determined, with the WHO report identifying knowledge gaps. Whilst some in the medical fraternity dismiss detoxification as quackery, bioaccumulation exists and is measurable. Research on human biotransformation and elimination systems and pharmacognostical approaches that support biotransformation of POPs, more specifically PCBs, BPA, phthalates, dioxins and furans, is urgently needed. In addition, mitigation strategies should be widely encouraged. CAM therapists who specialises in bioaccumulation and biotransformation may have a valuable role to play in detoxifying harmful EDCs in human beings. Further research into this area is warranted and the results and applications of this research have the potential to reduce endogenous EDCs and POPs in humans and thus, have the potential to lead to improved global health outcomes.
