Can helicobacter pylori infection increase the risk of variceal bleeding in patients with liver cirrhosis?

Abstract

Background and study aims: Gastro-oesophageal varices carry high risk of bleeding which may be fatal in some circumstances. Many patients with varices have Helicobacter pylori (H. Pylori) infection in their gastric mucosa. The relationship between H. Pylori infection and the incidence of upper GIT bleeding was not well studied. Our study was aimed to study the role of H. Pylori infection in gastro-oesophageal variceal bleeding.

Patients and Methods: The subjects were 392 cirrhotic patients who were admitted to the Zagazig University Hospital to treat their gastro-oesophageal varices, consisted of 190 with upper GIT bleeding (bleeder group) and 202 with non bleeding episodes but came for prophylactic purposes either primary or secondary prevention (non bleeder group). For the diagnosis of H. Pylori infection, rapid urease test was done for endoscopic gastric biopsies.

Results: Gastro-oesophageal variceal bleeding was seen in 31.6%(n=60) of the H. Pylori infected patients and in 68.4%(n=130) of the no infected patients (total number was 190 patients) (P<0.001). The H. Pylori infection was associated with low incidence of bleeding in patients with gastro-oesophageal varices.

Conclusion: These results suggest that H. pylori infection may have a protective effect against gastro-oesophageal variceal bleeding.

Keywords: helicobacter pylori, gastro oesophageal varices, upper git bleeding

Introduction

H. Pylori is a gram-negative bacterium which lives in gastric mucosa, is the main cause of gastritis type B, peptic ulcer disease and Mucosa-associated lymphoid tissue (MALT) lymphoma.

Portal hypertension in patients with cirrhosis is the cause of many dangerous complications, such as hepatic encephalopathy, ascites, and gastro-oesophageal variceal bleeding. Gastro-oesophageal variceal bleeding is the cause of more than one-third of deaths in patients with liver cirrhosis. H. Pylori infection has a role in some diseases as peptic ulcer portal hypertensive gastropathy and hepatic encephalopathy. However, the role of H. Pylori infection is not well studied in cirrhotic patients with gastro-oesophageal variceal bleeding. The aim of our study was to assess and clarify the effect and the correlation between H. Pylori infection and bleeding from gastro-oesophageal varices in patients with liver cirrhosis and portal hypertension.

Patients and methods

This cross-sectional study was conducted in the Gastroenterology, Hepatology and Endoscopy unit of Internal Medicine department, Zagazig University Hospital from December 2015 to may 2017. Informed consent and agreement of ethical committee was obtained from all patients.

A total number of 392 patients with gastro-oesophageal varices were admitted to the hospital for treatment, the patients were classified into two groups:

a. Group A: 190 patients with active upper GIT bleeding (bleeding group).
b. Group B: 202 patients without active upper GIT bleeding for elective endoscopy to prevent recurrent bleeding (non-bleeding group).

Inclusion criteria

Subjects included in this study were cirrhotic patients, with age group 25-65 years old, both males and females.

Exclusion criteria

i. Patients with known peptic ulcer disease.
ii. Those who receiving anti-ulcer treatment in the last three months and still receiving proton pump inhibitors (PPI) or H2 receptor blockers.
iii. Those previously diagnosed to have H. pylori infection and those who had undergone or were currently undergoing H. pylori eradication.

Methods

All the included patients will be subjected to the following: Full history taking, full clinical examination, laboratory investigations including: CBC, liver function tests as prothrombin time, serum albumin, Alanine Aminotransferase (ALT), Aspartate Aminotransferase (AST), total and direct bilirubin, kidney function tests including blood urea and creatinine.

Abbreviations: iNOS, inducible nitric oxide synthase; PPI, proton pump inhibitors; ALT, alanine aminotransferase; AST, aspartate aminotransferase; EVL, endoscopic variceal ligation; EIS, endoscopic injection sclerotherapy; SPSS, statistical package for social science; MALT, mucosa-associated lymphoid tissue

Conclusion

These results suggest that H. pylori infection may have a protective effect against gastro-oesophageal variceal bleeding.

Keywords: helicobacter pylori, gastro oesophageal varices, upper git bleeding

Abdominal ultrasonography, upper gastrointestinal Endoscopy

Endoscopic variceal ligation (EVL) or endoscopic injection sclerotherapy (EIS) with 5% ethanolamine oleate was performed for securing oesophageal varices and injection with histocryl was performed for securing gastric varices.

A. Child-Pugh classification was done on admission by using parameter of serum bilirubin, serum albumin, prothrombin concentration, hepatic encephalopathy and ascites.

B. Rapid urease test was done for gastric biopsies to diagnose H. Pylori infection by using (rapid urease test kits, Kimberly-clark; Ballard, USA).

Statistical analysis

a) The collected data were computerized and statistically analyzed using SPSS program (Statistical Package for Social Science) version 20. Qualitative data were represented as frequencies and relative percentages.

b) Chi square test (χ²) and Fisher exact was used to calculate difference between qualitative variables as indicated. Quantitative data were expressed as mean ± SD (Standard deviation). Independent T test was used to calculate difference between quantitative variables in two groups in normally distributed data. The significance Level for all above mentioned statistical tests done. The threshold of significance is fixed at 5% level (P-value) *P value of >0.05 indicates non-significant results. *P value of <0.05 indicates significant results.

Results

Two hundred and fifty nine of our cases were males with a percentage of 66% and one hundred and thirty three patients were females with a percentage of 34%. Among of them one hundred and ninety patients presented with upper GIT bleeding with a percentage of 48.4% and two hundred and two patients were non bleeders with percentage of 51.6% (admitted for elective upper endoscopy). According to Child-Pough scoring system: The patients were divided as follow shown in Table 1.

By abdominal ultrasound 43 patients with a percentage of 11% having hepatic focal lesions, 313 patients with a percentage of 79.8% having splenomegaly and 36 patients with a percentage of 9.2% having ascites. Upper GIT endoscope was done to all patients for diagnosis and treatment gastro-oesophageal varices. The endoscopic findings of the patients were listed in table (2,3) as follow shown Table 2 & 3.

Rapid urease test was done for all biopsies taken for diagnosis of H. Pylori infection and the results were as follow:

H. Pylori infection was 60 patients in group A and 112 patients in group B with a total number of 172(43.8%) (Figure 1). Gastro-oesophageal variceal bleeding was seen in 31.6%(n=60) of the H. Pylori infected patients and in 68.4%(n=130) of the no infected patients (total number was 190 patients) (P<0.001). Thus, the non-bleeding patients had a higher rate of H. Pylori infection than bleeding patients with a statistically significant difference between the two studied groups as regard infection with H. Pylori (Table 4).

Discussion

Patients with liver cirrhosis and portal hypertension carry high risk of upper GIT bleeding. Many risk factors have been reported for bleeding from esophageal varices .Systemic risk factors such as ascites, hepatic functional reserve, HCC and endotoxemia. Local risk factors include esophagitis, degree of gastropathy, size of the varices, red colour sign, alcohol and the use of an NSAID. The hemodynamic factors as high portal pressure, and high intravascular pressure with variceal wall tension.

Portal hypertensive gastropathy include changes in mucosa of the stomach of patients with liver cirrhosis It is associated with tortuosity and dilation of the submucosal vessels, increased area of the gastric mucosa occupied by vessels and thinning of the vascular wall, and there is activation of growth factors and cytokines, such as

![Figure 1 shows Prevalence of H. Pylori infection in all cases included in this study.](image-url)
Can helicobacter pylori infection increase the risk of variceal bleeding in patients with liver cirrhosis?

H. Pylori is considered a risk factor for peptic ulcer in patients with cirrhosis. There is a significant increase in the production of inducible nitric oxide synthase (iNOS) in patients with portal hypertensive gastropathy. H. Pylori also increases expression of iNOS.

Initially we expected that when inflammation from H. Pylori infection is added to the surface mucosa of varices, mucosal breaks can occur easily and become a triggering factor for bleeding varices. However, the incidence of gastro-oesophageal variceal bleeding was significantly lower than expected in patients infected with H. Pylori. It may be explained by atrophic gastritis induced by H. Pylori infection which leads to decreased acid production which has harmful effect on variceal wall.

In some studies, it has been reported that the prevalence of H. Pylori infection is significantly lower in patients with gastro-oesophageal reflux disease than without. In addition, another report has found that H. Pylori infection inhibits reflux esophagitis by inducing atrophic gastritis. These data confirmed that gastric acid may be involved in esophageal bleeding because of variceal rupture.

Conclusion

The results of our study demonstrated that H. Pylori infection was associated with low incidence of bleeding in patients with gastro-oesophageal varices than without and even may have a protective effect on variceal bleeding through induction of atrophic gastritis and concomitant hypoacidity.
