Research on correlation between compression index (Cc) and other properties of soil for geotechnical design in coastal regions of Vietnam and cambodia

Abstract

Compression index (C_c) takes an important role in settlement prediction for engineering foundation. Value of C_c depends heavily on methods of taking sample, sample transportation, quality of laboratory testing equipment, laboratory staff experience. These works are not well controlled in developing countries such as Vietnam and Cambodia. Our research is to find out the most suitable correlation between C_c and other properties of weak soil layer in coastal regions of Vietnam and Cambodia. From that, authors propose a new formula showing the correlation between C_c and liquid limit (LL) of the soil layer for geotechnical design in Vietnam and Cambodia.

Keywords: compression index (cc), correlation, settlement

Introduction

International and Vietnamese scientists have proposed many correlations between physical and mechanical properties of soil for geotechnical design. But, only some of them are suitable for construction areas in Vietnam and Cambodia. This research will find out and propose some suitable correlations between some physical and mechanical properties of very soft to soft dark grey lean Clay in these areas. This weak soil layer has wide distribution and great thickness and greatly affects stability and settlement of construction works, but methods of taking sample, sample transportation, quality of laboratory testing equipment, laboratory staff experience and in-situ tests performed in the layer do not often meet the technical requirements for geotechnical design in Vietnam and Cambodia.

Data used in this paper are received from geotechnical investigation results in Quang Ninh, Nghe An, Soc Trang, Quang Ngai provinces, Ho Chi Minh city of Vietnam and Sihanoukville province of Cambodia. Research areas are shown in Figure 1 below.

Figure I Location map of research areas.

Overview of the study subject

The meaning of compression index (C_c) in geotechnical design

Compression index (C_c) is mentioned in a lot of construction standards in Vietnam and other countries in the world. It takes an important role in settlement prediction for engineering foundation.

Settlement prediction of each soil layer is calculated by the following formula:

$$\Delta S_c = \frac{C_c}{1 + e_0} H_i \log \left(\frac{\sigma'_o + \Delta \sigma'}{\sigma'_o} \right)$$

Where:

 ΔS_c : Consolidation settlement of the soil layer;

C_c: Compression index;

H_i: The thickness of the soil layer.

e_o: Initial void ratio.

 σ'_{0} : Initial stress at the middle of the soil layer.

 $\Delta \sigma$ ': Effective stress increase at the middle of the soil layer.

Therefore, the evaluation and determination of correlation between Cc and other properties of soil have extremely important meaning in geotechnical design.

Research areas in vietnam and cambodia

Vietnam's coastline stretches the entire length of the country, about 3260kilometers and just about 443kilometers for Cambodia. Vietnam and Cambodia have a tropical monsoon climate, large rainfall amount.

The geological structure of the research areas contains a thick, soft to very soft marine dark grey lean clay layer with the thickness of

5 to 50m (Figure 2) which creates dangerous engineering-geological processes, including land subsidence and deformation of buildings and other structures.

Figure 2 Distribution of marine clay in South East Asia (Cox, 1968).

Average value of some physical and mechanical properties of the layer is as follows:

I.	Natural moisture content (W):	55.8-53.3%;
II.	Natural unit weight (ρ) :	1.62-1.58g/cm ³ ;
III.	Natural void ratio (e _o):	1.470-1.400;
IV.	Liquid limit (LL):	45-60%;
V.	Plasticity index (PI):	16.9-15.9%;
VI.	Cohesion (c):	7.0-8.9kPa;
VII.	Internal friction angle (ϕ) :	5°33' - 5°49';
VIII.	Compression index (Cc):	0.40-0.58.

Table 2 Determination of Cc at Cai Lan Port - Quang Ninh province

Some correlations between Cc and other properties of soil

There are a lot of formulas showing the correlation between C_o and other properties of soils proposed by famous scientists in the world. Below some formulas showing correlation between C_c and other properties such as void ratio (e₀), moisture content (W), liquid limit (LL), plasticity index (PI) are listed in Table 1.

Table I Some correlation between Cc and other properties of soil

Formula	Proposed by
C _c =0.007(LL - 7.0%)	Skempton (1944)
$C_c = 1.15(e_0 - 0.35)$	Nishida (1956)
C _c =0.29(e ₀ - 0.27)	Hough (1957)
$C_c = 0.256 + 0.43(e_0 - 0.84)$	Cozzolino (1961)
C _c =0.0046(LL-9.0%)	Cozzolino (1961)
C _c =0.009(LL -10.0%)	Terzaghi & Peck (1967)
C _c =0.75(W-0.5)	Sowers (1970)
C _c =0.006(LL-9.0%)	Azzouz et al. (1976)
C _c =0.037(e ₀ - 0.003LL - 0.34)	Azzouz et al. (1976)
$C_c = 0.01 (W-7.549\%)$	Herrero (1983)
C _c =0.54(e ₀ -0.23)	Moh a kol. (1989)
C _c =0.007(LL - 7.0%)	Moh a kol. (1989)
C _c =0.009(LL - 8.0%)	Tsuchida (1991)
$C_c = 0.014(PI + 3.6\%)$	Sridharan & Nagaraj (2000)

The suitable correlation between Cc and other properties of soil in coastal regions of vietnam and cambodia

Based on data received from the geotechnical investigation results in Quang Ninh, Nghe An, Soc Trang, Quang Ngai provinces, Ho Chi Minh city of Vietnam and Sihanoukville province of Cambodia carried out from 2010 to 2016, correlation between C_s and other properties of weak soil layer in coastal areas of Viet Nam and Cambodia is analysed Table 2-8.

Some formulas in Table 1 and a formula proposed by authors $[C_c=0.009(LL-2.0\%)]$ are used for analysis. The values of C_c determined by these formulas are compared with C_c received from laboratory testing results. The C_c received from laboratory testing results is considered as standard values for analysis. Analysis results are shown in tables and figures below (Figure 3-9). Correlation between C_c & other properties of soil at Sihanoukville province. The research results show that the value of C_c received from Terzaghi & Peck's formula is close to C_c received from laboratory testing results; and C_c received from formula proposed by the authors is not deferent from C_c received from laboratory testing results. C_c

Conclusion and recommendation

In coastal regions of Vietnam and Cambodia, there is a thick, soft to very soft marine dark grey lean clay layer which creates dangerous engineering-geological processes, including land subsidence and deformation of buildings and other structures.

Compression index (Cc) takes an important role in settlement prediction for engineering foundation. Value of $C_{\rm c}$ depends heavily on methods of taking sample, sample transportation, quality of laboratory testing equipment, laboratory staff experience. These works are not well controlled in developing countries such as Vietnam and Cambodia. The research focuses on the correlation between $C_{\rm c}$ and other properties of the layer. Research results show that the correlation between $C_{\rm c}$ and Liquid limit is the tightest. The formula proposed by Terzaghi & Peck is suitable correlation between $C_{\rm c}$ and LL. The authors revised Terzaghi & Peck's formula and proposed a new formula $[C_{\rm c}{=}0.009(LL{-}2.0\%)]$. The research results show that this formula is the most suitable one for the correlation between $C_{\rm c}$ and LL of the layer in research areas.

We recommend to use the correlation C_c=0.009(LL-2.0%) for the clay layer in coastal regions of Vietnam and Cambodia.

Acknowledgements

The authors wish to thank Mr. Dao Xuan Quang, general director of EGS Vietnam Ltd, Transport Engineering Design Incorporation (TEDI) and Vietnamese colleagues for providing us input data. We also want to thank Mr. Elan Phillips for his valuable comments on the manuscript.

Conflict of interest

The author declares no conflict of interest.
