Children and adolescents with negative social jet lag value

**Keywords:** Social jetlag; Daytime sleepiness; Cognitive performance; Sleep; Wake-up time

**Abbreviations:** SJL: Social Jet Lag; AP: Academic Performance; HDL: High-Density Lipoprotein

**Opinion**

The discrepancy between work (school) and free days can be described as ‘social jetlag (SJL),’ and SJL is the absolute difference in midpoints of sleep between work (school) nights and free nights.¹ SJL refers to a mismatch between biological and social timing.² SJL is known to be associated with variable problems³ such as behavioral problems, daytime sleepiness, academic achievement, cognitive performance, metabolic risk and depression scores, especially among those who had a SJL of more than 1 hour.³ However, to my knowledge, few descriptions have been made on negative SJL values. In my recent study,⁴ to my surprise, problems on negative SJL (an earlier mid sleep time on free days compared to work (school) days) have been found. In the current brief introductory opinion, I would like to raise the presumable unfavorable impact on children and adolescents with negative SJL values.

In order to determine the lifestyle habits including SJL significantly associated with self-reported academic performance (AP) in children in grades 5 to 12 (aged from 10 to 18 years) in Japan, a total of 2,114 completed questionnaires⁵ were analyzed. In this study, children were categorized into five groups according to their SJL distribution: -1 or less (SJL 1, n=19), more than -1 and 0 or less (SJL 2, n=452), more than 0 and 1 or less (SJL 3, n=1082), more than 1 and 2 or less (SJL 4, n=459), more than 2 (SJL 5, n=102). Consistent to former reports,⁶ this study⁷ showed that the mean self-reported AP of SJL 3 was significantly higher than that of SJL 4 and 5.⁸ In comparison with SJL 3 students, SJL 5 students were found to have a longer screen time, a later bed time, and a shorter weekend sleep duration, resulting in a later weekend wake-up time with a longer weekend sleep duration. In addition, breakfast and bowel habits of SJL 3 were better than that of SJL 5⁹.

Interestingly, nearly a quarter (22.3% [471/2114]) of whole students of the above-mentioned study was categorized into SJL 1 and 2, who had a SJL of 0 or less than 0 hours. Wong et al. [3] described that 68 out of 447 analyzed adult participants (15.2%) had a SJL of less than 0 hours. However, they did not mention in details on these negative SJL value participants, although they found that greater SJL associated positively with triglycerides, fasting insulin, insulin resistance, waist circumference, and body mass index, and negatively with HDL-cholesterol.

The mean self-reported AP of SJL 1 in the above-mentioned study was significantly worse than that of SJL 3. In addition, compared with SJL 3 students, SJL 1 students showed a significantly higher male rate and had a shorter weekend sleep duration, a shorter weekend screen time, an earlier weekend bed time, a later weekday wake-up time, and an earlier weekend wake-up time. Moreover, SJL 1 students had a higher physical activity value than SJL 3 students. SJL 1 students in the study might be forced to wake up early in the weekend morning to practice physical activity, resulting in suffering from sleep loss and poor self-reported AP. Indeed, in my out-patient clinic, several students with complaints of daily sleepiness during school lesson confessed that they are active athletes and are obliged to join away matches almost every weekend, resulting in the shortage of sleep because of the many school obligations in addition to their practice as an athlete. I advised them to have a sleep during daily school lesson, which might be forced to wake up early in the weekend morning to practice physical activity, resulting in suffering from sleep loss and poor self-reported AP. Indeed, in my out-patient clinic, several students with complaints of daily sleepiness during school lesson confessed that they are active athletes and are obliged to join away matches almost every weekend, resulting in the shortage of sleep because of the many school obligations in addition to their practice as an athlete. I advised them to have a sleep during daily school lesson,
Children and adolescents with negative social jet lag value

if they selected their priority on athlete’s practice.

On SJL 2, their average self-reported AP was better than both SJL 4 and 5, but showed no significant difference with SJL 3. A SJL value of -1 or less might be of negative influence on both mental and metabolic conditions.
